Human–Computer Interaction Research in Information Retrieval

Shin-jeng Lin

Department of Business Administration, Le Moyne College, Syracuse, New York, U.S.A.

Abstract

Human–computer interaction is a very important topic in studying computerized information retrieval systems, as it takes into account both the human searchers and the information system features. This entry surveys the major research streams and applications of interactive information seeking and retrieval. It also presents how the expectations and requirements for interactive information seeking and retrieval have been expanded and what the challenges are ahead for evaluating such systems.

INTRODUCTION

Human–computer interaction research has increasingly become an important component of information retrieval studies, as the information infrastructure has become largely dependent on computer technology, at personal, group, or organizational levels.

Human–computer interaction research in information retrieval is about identifying the key characteristics of searchers, tasks, and contexts, that affect the search tactics and behaviors of searchers and proposing system features for proper supports. Various streams of research are under this umbrella, including:

1. Interactive information retrieval, which Ingwersen^[1] defines as “the interactive communication processes that occur during the retrieval of information by involving all the major participants in information retrieval (IR), i.e., the user, the intermediary, and the IR system.”
2. Information retrieval in context, or situated information retrieval, i.e., to incorporate aspects of the searcher or environment that are typically not reflected in queries or search statements, such as the time, place, and history of interaction, the tasks motivating the interaction and the technical possibilities of the information systems.
3. Human–computer information retrieval, which “aims to empower people to explore large-scale information bases but demands that people also take responsibility for this control by expending cognitive and physical energy”.^[2]
4. Cognitive information retrieval, which takes into account interface issues, the role of information retrieval system interaction in the total range of people’s information behaviors, and the information situation, task situation, and problem situation of users when using an IR system (pp. 3,4).^[3]

This entry will first describe the history of how we get to this research paradigm in section “History” and then proceed to cover the major research streams in section “General Research Streams,” the applications and tools proposed and developed in section “Applications, Tools, and Techniques for Interactive Information Seeking and Retrieval,” the evaluation methods for studying the interactive information retrieval systems in section “Evaluation of Interactive Information Retrieval Systems and Interfaces,” the important conferences, workshops, organizations, and institutions in section “Important Conferences, Workshops, Organizations, and Institutions.” It will conclude with the expectation of the bright future for this research paradigm.

HISTORY

Information retrieval is defined as the process of searching a collection of documents with the goal of identifying documents pertaining to a particular topic.^[4,5] The process of information retrieval is inherently interactive between the information searcher and an information environment/system,^[6,7] as such a process depends on initiatives on the part of the information searcher, feedback from the information environment, and decisions on subsequent initiatives based on this feedback (p. 17).^[8]

The factors associated with both searchers (e.g., type, context of use, kinds of information needs, and immediacy of information needs, etc.) and systems (e.g., size and subject coverage of document collection or database, information representation, indexing methods, algorithms of matching queries against document collections, etc.) plus those associated with the interaction process between the two (e.g., revision of queries or search statements, search logics, and tactics) all could affect the performance of information retrieval.^[7,9–12]

Despite the interactive nature of the information retrieval process, the information retrieval field has its tradition in “system-centered” research or the matching paradigm, which focuses “solely” on improving the match between query terms and document representations, without taking into account the complexities of the users.^[11,13,14] A closely related research community takes the “user-centered” approach, mainly focusing on information seeking behavior/processes, as well as contextual, cognitive, and even affective factors related to such information seeking processes.^[1,15,16] While related, the two research communities hold a critical stance toward each other,^[17] and much of the user-centered research does not directly address the design of information systems. From the user-centered perspective, the term “information retrieval” is too confined to cover a wide spectrum of information searching phenomenon, as it implicitly connotes that the information searcher already has clearly-defined “information needs” and only needs to “retrieve” the documents from the system that can fittingly answer those needs. The uncertainty of user “information needs” that users are still struggling to form into shape is overlooked. In other words, if the user is not sure what he/she is or even should be looking for, how could the system possibly provide the best answer to his/her “information needs?” Information seeking, thus, is a preferred term over information retrieval in the user-centered studies.

The gaps between the two schools of thought are self-evident, as both have their significant shortcomings. The system-centered studies could contribute to effective information retrieval, but may not be efficient. The success of an information retrieval system totally relies on 1) whether the user can produce the queries that “perfectly” reflect the user’s information needs, which could be still evolving, and 2) on its own capability of matching its document collection against those “perfect” queries. It is a daunting, if not impossible, task, given that many studies have shown the non-specificity of “information needs.”^[4,18–21]

Moreover, the information retrieval process is more than just simply articulating queries and evaluating search outcomes.^[22] Marchionini^[23] argued that most of information retrieval systems focus on query formulation and results examination functions but ignore problem identification/clarification and information extraction.

Other common search tactics are found, including but not limited to, chaining, differentiating, and extracting, scanning, listing ideas, and many others to either tolerate uncertainty about “information needs” or develop the “information needs.”^[15,18,24]

In addition, the fact that the information retrieval process frequently takes place over multiple search sessions is often overlooked in system-centered studies.^[25–31] Failure to consider the nature, evolution or stages of the information seeking processes likely results in an IR system that requires more effort and time from the searchers to find satisfactory results.

Studies also have reported that searchers often engage in multiple tasks at the same time.^[28,32] By concentrating on the information retrieval task itself without considering its context or broadening its perspective, the questions of “could’ve” and “should’ve” linger, as other information tasks that are associated with information retrieval, such as question answering, information assimilation, and personal knowledge management, are isolated and thus the information flow and transition among them not supported.

Traditional IR systems are designed primarily to support individuals. Yet, individuals often need to collaborate on information seeking, searching, and retrieval.^[33] Research on information retrieval thus expanded to collaborative information seeking and retrieval, just as research efforts in Human-Computer Interaction expanded beyond the individual levels to support collaborative computer work. Research on collaborative information seeking and retrieval has drawn heavily from studies on computer-supported collaborative work (CSCW), information science, information retrieval, and human-computer interaction studies. Foster^[33] provided a literature review of the social and collaborative approaches to information seeking and retrieval in the four specific contexts: academy, industry, medicine, and the military. Understanding how people work together has direct implications on designing effective and efficient collaborative information retrieval applications.

The problems of user-centered studies are just the opposite to those of the system-centered ones. Vakkari and Järvelin^[34] noted that the user-oriented Information Science approach suspects the realism of the Computer Science system-oriented experimental approach, while the latter suspects the usefulness of the former. While user-centered studies have provided a great understanding of human information tasks and cognitive processes, they often failed to empirically demonstrate the effects and magnitudes of the factors that could affect the information seeking processes.^[35] Moreover, many of the studies under this paradigm do not pragmatically suggest possible system solutions for the problems identified.

The differences in the research foci of the “system-centered” vs. “user-centered” research streams were mainly due to the lack of interdisciplinary studies in the earlier IR research community. The “system-centered” IR studies were likely from the computer science discipline, while the “user-centered” IR studies were likely from the disciplines of library and information science, communication, etc.

The cry for the interaction approach that takes both the system and the user into account was heard first in the early 1970s.^[36,37] For example, the workshop on The User Interface for Interactive Search of Bibliographic Databases is considered the first occasion on which the general problem of user interfaces for computer systems was raised.^[6] The effort to bridge the two camps went extensively into the 1980s and 1990s, and has continued today.

With more and more information systems going electronic and an increasing amount of information collections being digitized, the fields of human-computer interaction (HCI), library and information science (LIS) and computer science (CS) inevitably converge on interactive information retrieval/seeking. On the one hand, HCI sheds light on how to bridge the user-centered vs. system-centered paradigms with the HCI concepts and research models being applied to the studies of IR systems.^[11,38-42] On the other hand, the work of the LIS researchers^[26,34,43-55] and CS researchers,^[56-64] who respond to this outcry, are HCI per se, as they aim to streamline the collaboration between the human searchers and system enablers to improve the overall performances and outcomes of information retrieval processes by considering both users characteristics and system features in the design of information retrieval systems.

GENERAL RESEARCH STREAMS

Major Theories and Models on HCI Research in IR

Although the major theories and models on HCI research in IR might utilize some HCI concepts, such as two-way communication between message sender and receivers and interaction with texts or content rather than information systems (p. 857),^[65] they hardly adopt entirely well-established HCI theories or models. For example, the Goals, Operators, Methods, and Selections model (GOMS), a human information processor model,^[66] is considered best suitable for routine, more structured and predictable information tasks and behavioral patterns.^[67,68] The information seeking/retrieval process could be too interactive and too highly complex to be explained by GOMS.^[65,68,69] Consequently, the major theories and models on HCI research in IR are likely to be developed from within the field of information science and meet the following criteria:

1. They must enumerate the variables that are associated with both users and computerized IR systems.
2. They must describe, explain and/or predict the interactions between the variables associated with the human searcher and the computerized IR system for the information retrieval/seeking tasks.
3. The description, explanation, and/or predictions of interactions between the searchers and the IR systems would serve as a conceptual framework to provide design implications for IR systems.

Ingwersen's cognitive IR theory

Ingwersen's cognitive IR theory^[1,17] identified cognitive processes that occur in information processing. The main

model components are 1) IR system objects which consist of text/knowledge representation (e.g., meta data), semantic entities like full text and pictures, 2) IR system setting, including search languages/IR techniques, database structure, indexing rules/computational logics, 3) intermediaries that facilitate the information retrieval process, e.g., computer interfaces, human intermediaries and 4) individual searchers' cognitive space, including work task/interest, current cognitive state (the currently known, drawing upon emotions, tacit knowledge, and external factors influencing the searcher), problem space, uncertainty, information need, and information IR behavior, and 5) social/organizational environment, including such variables as domains, strategies, and tasks and preferences.

Ingwersen described the following interactions among these model components: 1) Users interact not only with IR systems, but with information objects, i.e., "texts," "documents," etc.; more specifically, it is the cognitive space of the user that interacts with the "information space" of IR systems; 2) The social and organizational environment influences and shapes the individual cognitive space; 3) From the system design perspective, for the five model components to interact to produce the more effective IR outcome, each of them can "model" or profile how other components would behave cognitively; and 4) The success of the IR process relies on the polyrepresentation in IR. Searchers' queries requested can be enhanced with problem/goal statement and work task/interest description, because in the searchers' cognitive space, work task and interest domains define what is known (current cognitive state) and prompt for what is unknown (problem space) and the gap in between the two (information need). In the information space of IR, different methods of knowledge representations can facilitate the matching of the representations of searcher's cognitive space against semantic entities.

Saracevic^[11] pointed out that the strength of the Ingwersen's model lies in the detailed description of the interactions between the searchers and the systems, while the weaknesses of the model could be its testability and application to the evaluation of interactive IR system. Such an assessment is accurate to some degrees, as the main purpose of the Ingwersen's model was to inform the design of an interactive IR system with a descriptive account of the essential processes from both the user and system perspectives; the model did not intend to enumerate the key performance variables for evaluation.

Belkin's episode model

Belkin's episode model^[22,70,71] postulates that because the searchers may not always be capable of best representing their information problems with effective query terms, a variety of information interactions to

clarify the information problems would be necessary. Sixteen types of information seeking strategies are identified and characterized with four dimensions or factors, each of which has two possible values: method of interaction (scanning vs. searching), goal of interaction (learning vs. selecting), mode of retrieval (recognition vs. specification), and resources considered (information vs. meta information). Based on an empirical study of knowledge workers, Cool and Belkin^[72] extended these facets to create information behavior facets, consisting of access, objects interacted with, common dimensions of interaction, and interaction criteria. The access facet includes two sub-facets from the four original ones: method and mode of interaction. The “objects to interact with” facet includes level (information vs. meta-information), medium (e.g., image, written text, speech, etc.) and quantity (e.g., one object, set of objects, database, etc.). The “common dimensions of interaction” facet entails information objects (part vs. whole), systematicity (random vs. systematic), and degree (selective vs. exhaustive). The “interaction criteria” facet is about evaluation criteria or tactics, including accuracy, alphabet, authority, date, person, etc.

Belkin and his colleague suggested that all the information seeking strategies can be supported with a combination of a variety of IR techniques, including representation, comparison, summarization, navigation, and visualization. The initially proposed idea was to use a script-based dialogue to assist the searchers in utilizing proper information seeking strategies that are optimally supported by specific combinations of IR techniques. Yuan and Belkin^[54] prototyped an IR system, that simply provides a small selection of information seeking strategies to the searcher. They found that subjects using the prototyped system were likely to spend a fewer number of iterations in submitting queries and the query was likely to be longer than the baseline system. They also found that in terms of usability, the integrated system was significantly easier to use and significantly more useful than the baseline system.

Saracevic^[11] made the following critiques of Belkin’s episode model. On the plus side, the model directly addresses a greater range of various interactions in the activity level that are so specific that they can easily be mapped onto the designed system features. On the potentially negative side, Saracevic wondered whether the scripts identified would be insufficient to reflect the full complexity and extension of human–computer interaction in IR. However, the Belkin’s episode model has proven a great starting point in designing and evaluating interactive IR system. The fact that Yuan and Belkin^[54] only focused on a portion of the model not only shows the complexity of the model that is too much to be covered in one single system, but also demonstrates the practical applicability of the model in designing and evaluating IR system artifacts.

Saracevic’s stratified interaction model

Saracevic’s stratified interaction model^[7,11,73] borrows from the concepts elucidated in HCI and from the notions incorporated in the stratification theory in linguistics and communication. The model postulates that the IR interaction is a dialogue between the participants, searcher and “computer,” through an interface with the main purpose being to affect the cognitive state of the searcher for effective use in order to apply a found solution to an information problem or task at hand. The model components are users (with such variables as knowledge, intent, and belief, etc.) related to a situation (task, problem-at-hand) within an environment, while interacting with computers to seek for/retrieve information. “Computer” is depicted as having computational resources and capacities, but also separately informational resources—“texts” as cognitive structures, representations, meta-information about texts, and informational and computational resources, and possibly other information for adaptation to different kinds of interactions and user intents.

The model depicts three levels of interaction between the searcher and the system and in some ways, seems to integrate the Belkin’s model with Ingwersen’s. First, it is on the surface level, where the user engages in a variety of interactions with the IR system as portrayed in Belkin’s model. Second, on the cognitive level, users interact with the “texts” (including images, data, and their representations) in the information resources, considering them as cognitive structures, to learn or to assimilate information in order to update their current cognitive state and revise the problem space, as argued by Ingwersen. Third, on the situation level, like Ingwersen, it is about how the environment interacts with or affects the searcher’s cognitive activity. However, Saracevic emphasized the effects of the application of the information found to the information problem at hand. Utility becomes a prominent relevance feedback criterion, which could change the information problem at hand and affect the decisions made.

Saracevic^[73] further extended the stratified model to encompass specific processes or phenomena that play a crucial role in various IR interactions, including the notion of relevance, user modeling, and feedback types. For the notion of relevance, the stratified model helps distinguish between the following manifestations of relevance as presented in Table 1.

For user modeling, the stratified model helps identify eight types of communication factors or artifacts that manifest the interactions taking place during IR processes, as summarized in Table 2.

For relevance feedback, the stratified model of IR interaction has served as a framework to observe and categorize the following different relevance feedback types in IR in Table 3.

Spink and Saracevic^[7] further elaborated the stratified interaction model with how relevance feedback is

Table 1 Types of relevance identified from the stratified model.

Type of relevance	Definition	Inferred criteria
System or algorithmic relevance	Relation between a query and information objects (texts) in the file of a system as retrieved, or as failed to be retrieved, by a given procedure or algorithm	• Comparative effectiveness
Topical or subject relevance	Relation between the subject or topic expressed in a query, and topic or subject covered by retrieved texts, or more broadly, by texts in the systems file, or even in existence	• Aboutness
Cognitive relevance or pertinence	Relation between the state of knowledge and cognitive information need of a user, and texts retrieved, or in the file of a system, or even in existence	• Informativeness • Novelty • Information quality
Situational relevance or utility	Relation between the situation, task, or problem at hand, and texts retrieved by a systems or in the file of a system, or even in existence	• Usefulness in decision making • Appropriateness of information in resolution of a problem • Reduction of uncertainty
Motivational or affective relevance	Relation between the intents, goals, and motivations of a user, and texts retrieved by a system or in the file of a system, or even in existence	• Satisfaction • Success • Accomplishment

represented by the interplay between levels (i.e., the cognitive, affective and situation levels on the user side and the engineering, processing, and content levels on the system side), giving rise to the following types of feedback in Table 3. But Spink and Saracevic^[7] stopped short of illustrating how the engineering, processing, and content dimensions of IR systems can make use of this feedback in supporting the searchers. Kelly^[50] examined the decisions during interactive information retrieval as to what to examine, retain (save, print), reference, annotate, and the like. Such decisions are assumed to indicate relevance implicitly, which would be very operationalizable for IR systems to make use of and support the searchers.

Saracevic^[11] himself noted that the strength of the stratified model lies in decomposition of different types of interactions as related to different elements involved, while the decomposition is not easy and depiction of interplays between levels is hard to specify and consequently the model is difficult to test. But the works of Saracevic^[73] and Spink and Saracevic^[7] have provided a positive direction to test the model by focusing on the manifestations of specific interactions or communications in IR processes, such as search terms, relevance feedback, etc.

Bates's cascade of interaction model

Bates's cascade of interaction model^[74] proclaims that the design of IR systems needs to take into account many design layers, including user understanding and motivations, user searching activities, interface design, search capabilities, system front end, search engine, information in searchable form, database structure, computer system, network, actual indexing, system of metadata and information content. The term, "cascade," is to describe how design features of earlier layers would affect the success

of those of later layers, while the latter could affect the effectiveness of the former.

Although the cascade model is neither a human-computer interaction model nor an interaction in information retrieval model per se (p. 385),^[74] it, as a design model for operational online IR systems, in a way, does summarize Bates's series of work^[12,75,76] in depicting how different factors concerning both the information searchers and the IR systems affect the performance of information seeking and retrieval. For example, the details of user search capabilities have been described by Bates.^[12] Moreover, the different design layers in the cascade model respectively correspond to the factors about the system infrastructure (i.e., the upper left part of the model), the information infrastructure (i.e., the bottom left part of the model), the interface infrastructure (i.e., the middle part of the model), and the human searchers (i.e., the right part of the model). The interactions between the human searchers and the interface infrastructure as well as between the human searchers and the information infrastructure are what substantiate human-computer interaction in IR.

Thus, even though the cascade model does not directly enumerate the variables that are associated with both users and computerized IR systems and instead focuses solely on the interactions of different layers of IR systems, the cascade model, under the broader context of Bates's works to date, still can be considered as a theoretical model in provision of a rich description of HCI in IR. Wilson et al.^[77] pointed out that Bates' cascade model actually can be perceived as extending the Saracevic's stratified model in greater detail with additional levels that interact and affect each other.

The strength of the cascade model is the emphasis on the tight coupling of different layers in IR system design. The weakness might be that additional works to directly identify variables in the layers in the cascade model may

Table 2 Factors or artifacts that manifest IR interactions identified through the stratified model.

1. Context	User's problem or task at hand; information seeking stage; information if any collected so far; expectations and other aspects underlying the question; user domain and problem knowledge; user plans.
2. Terminology and restrictions	Elaboration on and modification of concepts, terms, keywords, descriptors; generation of terms; specification of borderlines; restrictions such as to language, years; spelling of technical terms.
3. Systems explanations	Workings and technical aspects of system used; technical explanation of searching; characteristics of databases and documents in system; other possible information sources; obtaining texts; costs involved.
4. Search tactics and procedures	Selection and variation of terms, fields, morphology, logic in search statements; commands; selection and variation in magnitude and output sizes, formats, order; output specification; correcting mistakes.
5. Review and relevance	Review of tactics as to the output; evaluation of output sources or content; relevance judgments of and feedback from outputs; decisions or questions on what is wanted based on tactics or output.
6. Action	Description of an ongoing or impending activity e.g., thesaurus lookup, output formats, printing; explanation of what is happening.
7. Backchanneling—prompts, echoes	Communication prompts, fillers, acknowledgments, formulaic expressions etc. indicating listeners involvement, e.g., "O.K.," "Wow!" "Unhuh," "Right;" echoes and requests for repetitions e.g., "What?" "Pardon?" "Say that again"; pauses.
8. Extraneous	Utterances extraneous to the search interaction—greetings, formulaic courtesies, social comments, and questions; personal matters.

Table 3 Relevance feedback types identified with the stratified model.

Content relevance feedback	User query followed by an IR system output of retrieved items then judged by the user for relevance followed by a query or reformulation.
Term relevance feedback	User query followed by an IR system output of retrieved items and user selection of a new search term(s) from the retrieved output used in a subsequent query.
Magnitude feedback	User query followed by a judgment based on the size of the output from a query that effects the next query.
Tactical review feedback	User input followed by a strategy related judgment to display the search strategy history influencing the subsequent query.
Term review feedback	User input followed by a strategy related judgment to display terms in the inverted file influencing the subsequent query.

system, 3) search activity in which the searcher actually interacts with an IR system, 4) search contextual factors (e.g., time, perception of information availability, etc.), 5) information attainment (i.e., with the emphasis of interaction with text, particularly collected information objects), and 6) information use activity (e.g., like Saracevic's situational interaction level, with the emphasis on the impacts of the information sought on the evolution of the information problem, including such factors as decision making, cooperation, communication, commercial transactions, etc.). The model attempted a comprehensive list of variables that matter in successive multisessions information searches and depicted how the variables in these components interplay with each other.

The point of departure is the phenomenological perspective. MISE highlights how different search episodes of the same or similar information problems could be connected. MISE identifies eight different scenarios that a searcher could engage in successive searches based on the nature of how an information problem evolves. They are 1) transmuting information problems which a searcher learns to define or clarify over sessions, 2) spawned information problems which are derived from the main problem and take over the priority, 3) transiting information problems in which the solution of one information problem leads to the beginning of another, 4) rolled-back information problems resulting from the feedback of information use activity, 5) lost-answer problems in which the efficiency of locating the solution may be more important than effectiveness, 6) unanswered information problems, 7) cultivating information problems due to long-term interests, and 8) anticipating information problems foreseen to materialize in the near future.

The MISE model does not include the interface or computer intermediary directly in the model. Instead, it

still be needed to create a prescriptive evaluation procedure for interactive IR systems.

Lin's MISE model

The MISE model by Lin and Belkin^[25,26] and Lin^[51] continues in the footsteps of Ingwersen^[1,17] and Belkin et al.^[71,22] to incorporate the following components into the model: 1) searcher (including variables pertaining to problematic situation and information problems), 2) IR

uses the variables associated with the model components to characterize the problems a searcher could encounter during the different processes of search activity (i.e., articulation of information problems, navigation of the information space, evaluation of search outcomes, monitoring the state of the problem space) and consequently propose system features to mitigate the problems and support those processes.

Lin^[52] described an actual prototype, *PERsonalized and Successive Information Search Tools (PERSIST)*, which assists the searches for transmuting information problems; *PERSIST* enables the searcher to visualize his/her information collection by using representative words to label and categorize (i.e., explicit coding) his/her own information collection. Such an information collection and their associated labels/category terms can further be dynamically reorganized, expanded, modified, removed, and potentially filtered as the information problem of the searcher evolves. The design goal is to improve monitoring the state of the problem space and navigating the information space (e.g., revisiting information objects) to interact with information objects. The same goal is shared by Komlodi and her colleagues,^[53,78,79] who explored how automatically and manually recorded search histories can support information seekers in finding and using information. Komlodi^[80] and Komlodi and Soergel^[81] proposed three search-history-based user interface tools, including 1) user-manipulable search history displays, 2) a scratchpad interface to allow users to take notes and to save various granules of information and the search history, and 3) an organized collection tool to allow searchers to bridge the gap between finding and using information. All three of these user interface tools include functions to support planning, monitoring, evaluation, task integration, and context preservation.

The main strengths of the *MISE* model include broadening the scope of searcher-system interactions from single episode to multiple episodes and the apparent applicability from the conceptual model to the design and evaluation of system features (e.g., *PERSIST*). The major weakness could be that the system component is not as detailed and as well-layered as the stratified model and the cascade model; the design of system features to mitigate the problems occurred in the search process may not be as intuitive or as straight-forward as it could have been.

User-Centered Studies with Design Implications

More and more of the user-centered information search theories, models and their extensions have begun to explore the design implications for interactive information retrieval. Below are a few selected models.

Vakkari and his colleagues^[30,31,34,82–84] elaborated Kuhlthau's *ISP* model^[15,16] by providing more specific variable values in characteristics of information search

processes and how those variables interact with each other through time. Particularly, Vakkari and his colleagues have focused on how the number and type of search terms and operators and search tactics evolve over time as the information problem continues to develop, which could potentially have very operationalizable design implications for *IR* systems.

Cole^[85] described the interaction between searcher and system as a message coding and encoding process, proposing the idea of “enabling *IR* system” that would employ interactive devices (e.g., a visualized representation of comparing and contrasting concepts) to help the searcher clarify the state of his/her information problem. Extending Cole's work, Propper's model of the communication process, and Pask's conversation theory, Ford^[86] argued that an enabling *IR* system would be equipped with pedagogic structuring and intervention (e.g., computer-as-assisted learning technologies, such as conceptual maps, summaries, abstracts, classifications, and ontologies, etc.) to enable the searcher to process and build on his/her descriptive knowledge and procedural knowledge in need and help the searcher develop effective metacognitive information handling skills. Cole et al.^[47] made a similar argument as Ford, proposing the selection state-information channel model, urging an interactive *IR* system to develop mechanisms to interactively stimulate the searcher's cognitive ability in reaching a “selection state,” which can be seen as a refined, better-defined “information need” or information problem. In other words, instead of asking the searchers to represent their “information needs” that are still in need of clarification in query terms, the system should understand the task that prompts the searchers to seek for information and interact with them to clarify their “information needs.”

A growing number of user-centered studies focus on human information interaction, as opposed to human-computer interaction, in the process of interactive information retrieval and seeking. For example, Spink and her colleagues^[3,46,87–89] are developing the theory of human information behavior (*HIB*), postulating that information seeking should be tightly connected to other information processing behavior such as information organization and use. Under this theory, an interactive *IR* system could be integrated into a greater information system that would function for more than just information retrieval and should support other forms of information organization and use. Fidel et al.^[90] used the cognitive work analysis framework to observe how collaborative information seeking and retrieval takes place in the form of human information interaction, suggesting that interactive *IR* systems should include “mechanisms that support the interactions between the collaborating actors and enhance their access to one another's knowledge, ideas, and opinions or help them keep on track” (p. 951).

APPLICATIONS, TOOLS, AND TECHNIQUES FOR INTERACTIVE INFORMATION SEEKING AND RETRIEVAL

The theories, models and conceptual framework reviewed in section “General Research Streams” have directly or indirectly helped develop or called for the following interactive IR applications, tools, and techniques: user profiling,^[17,73] automatic or user-controlled relevance feedback to adjust or expand the users’ queries,^[7,73] computer-assisted learning technologies, such as conceptual maps, summaries, abstracts, classifications, and ontologies,^[86] pedagogic structuring and intervention mechanisms to help clarify and develop the searchers’ explicit representation of their information problems,^[44,47,86] supports beyond searchers’ representation of their information problems to facilitate overall information retrieval, such as browsing, learning, evaluating search outcomes, monitoring the evolution of information problems, annotating and preserving the context, and organizing information collections.^[22,25,26,53,71,78,79,91]

More detailed reviews of the types of the applications, techniques, and tools that have been developed during various periods of research in interactive IR can be found in the works of Shaw,^[39] Marchionini and Komlodi,^[37] and Savage-Knepshield and Belkin.^[6]

EVALUATION OF INTERACTIVE INFORMATION RETRIEVAL SYSTEMS AND INTERFACES

The evaluation of information retrieval systems have traditionally used the two measures, precision and recall, developed by the system-driven approach to IR,^[92–94] which typically takes place in controlled laboratory tests. These measures, however, are not the best to evaluate interactive IR systems, due to their restricted assumptions on the cognitive and behavioral aspects of the searcher,^[93] as described in the previous sections about the limitations of the system-centered approach on IR system design. In addition, finding information on the Web has its specific characteristics, making the applicability of the findings from traditional IR research questionable. Traditional IR research focuses on the development of retrieval strategies for relatively small, static, and relatively homogeneous text corpora. Web information, on the other hand, is massive in size, diverse and dynamic in content and format, and uncontrollable in quality. This makes it impossible to construct a representative test collection to support the conventional evaluation measures such as precision and recall.^[95]

Robertson and Hancock-Beaulieu (pp. 458–459)^[96] set forth three revolutions: the cognitive revolution, the relevance revolution and the interactive revolution. The cognitive and relevance revolutions require realism with

reference to the formation of information need, and relevance assessment processes. This means that an information need ought to be treated as a potentially dynamic concept, and the multidimensional (rather than just topically relevant) and dynamic nature of relevance should be taken into account. Likewise, relevance should be judged against the problematic situation in which the information need arises, not merely the explicit representation of that information need such as query or request statement, and it should be judged by the user. The “interactive revolution” requires the evaluation of IIR systems to include the user’s interactive information searching and retrieval processes, where evaluation of the search outcomes can be fluid itself, depending on the stage of information searches^[15] or the nature of the information problem.^[26]

While the user-centered information seeking studies potentially could help generate measures to fulfill the three requirements described above,^[97] they seldom directly design or implement an interactive IR system, let alone providing evaluation measurements. For the studies that do evaluate interactive IR systems, many of them quantify performance effectiveness as “relative” recall and precision ratios in spite of collecting non-binary-based relevance assessments^[97] or use the measures that are ad hoc in nature or not universally agreed upon (e.g., satisfaction, the amount of time required to complete a search task, etc). Also, the operationalization of these measures is often not derived from previously well-established questionnaire inventory items.

Performance Measures

Combining the elements from both system-centered and user-centered approaches, Borlund^[97] developed a hybrid evaluation approach to evaluate the systems “in a way which takes into account the dynamic natures of information needs and relevance as well as reflects the interactive information searching and retrieval processes.” The highlights of Borlund’s approach include 1) the emphasis in use of simulated work task situations to trigger simulated information needs and as the platform for the assessment of situational relevance in the context of IR, and 2) the development of alternative performance measures: relative relevance (RR), ranked half-life (RHL).^[98] The RR measure acknowledges the fact that different types of relevance^[99,100] are involved in evaluation of IR systems. The RR measure computes the degree of agreement between two results of relevance assessments; for example, one may represent the system’s output (algorithmic relevance) and the other the user’s subjective assessments (e.g., intellectual topicality, pertinence or situational relevance) of the retrieved output. The RR measure proposes a pragmatic solution of how to bridge the gap between subjective and objective relevance. The RHL indicator, a position-oriented measure, denotes the degree to which relevant documents are located on the

top of a ranked retrieval result, using two parameters: 1) the algorithmically ranked order, which represents a list of decreasing degrees of predicted objective relevance to the user's information need and 2) the applied subjective types and values of the relevance assessments representing the assessor's or user's interpretations of the ranked information objects.

There are several position-oriented single performance measures already developed. Based on the binary approach to relevant ranked information objects, Losee^[101,102] developed average search length (ASL), to indicate the expected position of a relevant information object in the ranked list of information objects. The expected search length (ESL) measure^[103] and Expected Search Duration (ESD),^[104] which is a modification of the ESL, both calculate the number of non-relevant information objects that the user has to view in the process of retrieving a chosen relevant information object. Seeking to estimate the cumulative relevance gain the user receives by examining the retrieval result up to a given rank, Järvelin and his colleagues^[105,113] developed cumulated gain (CG) and cumulated gain with discount (DCG). Both CG and DCG are positional oriented performance measures, but the CG measure builds upon the fact that highly relevant documents are more valuable than marginally relevant documents, while the DCG measure takes into account the relevance assessment behavior of users. The DCG measure has the following advantages not provided by the ASL or RHL measures: 1) it realistically weights down the gain received through the documents found later in the ranked list of results; and 2) it allows modeling the user persistence in examining long ranked result lists by adjusting the discount factor (p. 43).^[105]

Evaluation methods for non-traditional IR system, such as question-answering systems, have also been developed. Wacholder et al.^[106] described a procedure for quantitative evaluation of interactive question-answering systems and illustrated it with application to the High-Quality Interactive Question-Answering (HITIQA) system. Kelly et al.^[107] identified potential evaluation criteria for interactive, analytical question-answering (QA) systems by analyzing evaluative comments made by users of such a system.

Non-performance Measures

As stated in the major theoretical section of this entry, interactive information seeking is considered as a term that more properly portrays the actual interaction of the searcher with the IR system than interactive information retrieval, in that it covers a wider spectrum of the IR system user's search behavior. In addition, as Belkin et al.^[71,22] and Lin and Belkin^[26] pointed out, a variety of interactions other than querying and document matching is necessary in the design of interactive IR systems. Performance or retrieval effectiveness, alone, cannot completely

measure the success of an interactive IR system. Other important measures could concern efficiency (e.g., spending less time, cognitive efforts, cost effectiveness, etc., in seeking for the information), satisfaction, and goal-oriented effectiveness (e.g., meeting the goal of learning more about the subject) and will require more development in the near future.

Multi-dimensional relevance remains a key measure in interactive IR system. Saracevic^[73,100] provided an excellent review of relevance measures up to date.

Continuing the thread of research that promotes the idea of broadening information retrieval to its contexts,^[108] particularly the task that prompts for information retrieval,^[30,82-84] for achieving overall effectiveness and efficiency of information searches, Järvelin and Ingwersen^[105] proposed the nested contexts and evaluation criteria for task-based information seeking and retrieval in an interactive IR system. From the inner to the outer, the four contexts are the information retrieval context, the information seeking context, the work task context, and the social-organizational and cultural context. The information retrieval context is evaluated based on traditional IR performance measures such as recall and precision plus efficiency and quality of information/process. The information seeking context is evaluated in terms of usability and quality of information/process. The work task context is evaluated with the criteria like quality of information and work process/result. The social-organizational and cultural context is evaluated with social-cognitive relevance and quality of work task result.

Measures other than performance, such as described above, should increasingly affect the design and evaluation of interactive IR systems in the future, as the expectations and requirements of interactive IR systems continue to expand.

Validity and Reliability of Methodologies

In general, there is still a long way to achieve the robustness of evaluation measures in interactive information retrieval. Crudge and Johnson^[109] reported that the repertory grid technique is a suitable method of eliciting a definite set of constructs from an ordinary information seeker without instilling unacceptable levels of bias. Käkik and Aula^[110] present methods for controlling the complexity of user-centered evaluations of search user interfaces through within-subjects designs, balanced task sets, time limitations, preformulated queries, cached result pages, and through limiting the users' access to result documents. Kelly et al.^[111] investigate the relationship between questionnaire mode (pen-and-paper, electronic and interview) and subjects' responses to a usability questionnaire comprised of closed and open questions administered during an interactive IR experiment. Their findings suggest that researchers should use the interview mode to

elicit responses to closed questions from subjects and either pen-and-paper or electronic modes to elicit responses to open questions.

IMPORTANT CONFERENCES, WORKSHOPS, ORGANIZATIONS, AND INSTITUTIONS

The Text REtrieval Conference (TREC) is co-sponsored by the National Institute of Standards and Technology (NIST) and the U.S. Department of Defense. It started in 1992 as part of the TIPSTER Text program with the purpose of supporting research within the information retrieval community by providing the infrastructure necessary for large-scale evaluation of text retrieval methodologies. There have been four research tracks in TREC particularly pertaining to interactive information retrieval. The first and the one most relevant to interactive information retrieval is the interactive track. The participating groups developed a consensus experimental protocol and carried out studies with real users using a common collection and set of user queries, but used their own interfaces and each group could add additional focus on different research topics. Relevance feedback was a predominant topic in this track. The interactive track last ran as an adjunct to the Web Track in TREC 2003. The second is the Web track, featuring search tasks on a document set that is a snapshot of the World Wide Web. It last ran in TREC 2004. The third is the HARD track. The track aims to achieve High Accuracy Retrieval from Documents by leveraging additional information about the searcher and/or the search context, through techniques such as passage retrieval and using very targeted interaction with the searchers. It last ran in TREC 2005. The most current one is the question answering track, designed to take a step closer to information retrieval rather than document retrieval. The relevance to interactive IR studies lies in one of its sub-tracks, the complex interactive QA task.

Dumais and Belkin^[112] provided a great summary of the history and the evolving experimental framework of these interactive tracks in TREC. The summary reflected the following main points. First, the main contribution lies in the development of standard methodologies for studying interactive IR and comparing performance of interactive IR systems, including experimental designs, techniques for reporting event logs, and detailed narrative description of the search process. Second, many interesting systems have been developed to support interactive query formulation and reformulation as well as results presentations and explorations, which enabled the investigation of individual differences in the search process. Third, the reported results have been often variable or not statistically significant. Fourth, the lack of consistent and significant findings could be due to a small number of analysis units (e.g., tasks, subjects) and/or the complexity

of the interactive search process that is hard or insufficient to control during experiments. Fifth, the interactive tracks have continued to at least bring to the surface various important theoretical and pragmatic issues in conducting experiments with human participants. With the points above, various tracks that looked into interactive IR have ceased or evolved, while the goal remains the same: providing a focal point for work in designing and evaluating interactive IR systems.

The annual conferences of Special Interest Group on Information Retrieval (SIGIR) and Special Interest Group on Computer-Human Interaction (SIGCHI) in the Association for Computing Machinery publish many quality research articles and hold workshops on the topics of human-computer interaction research in information retrieval.

The MIT Computer Science and Artificial Intelligence Laboratory, or CSAIL, was born on July 1, 2003 by the merger of the Artificial Intelligence Lab and the Laboratory for Computer Science. It held the first Workshop on Human-Computer Information Retrieval in 2007.

The Annual Symposium of the Human-Computer Interaction Lab at the University of Maryland often includes research on human-computer interaction vs. information retrieval/information seeking. It marked its 25th anniversary in 2008.

CONCLUSION

Human-computer interaction research in information retrieval is a very rigorous research stream. It brings two distinctly separate research communities, system-centered information retrieval research and user-centered information seeking research, closer, if not together, for the same research goal: a more effective and efficient information search system that would take advantages of the respective strengths of humans and computers for interactions. In practice, the Web has also propelled highly interactive IR interfaces that demand that these two communities work together, as information retrieval on the Web faces the challenges of supporting different information interaction purposes and motivations from very diverse end users who may have unpredictable information seeking behaviors.^[2,95]

Many studies in the field of CS have started to treat the user as a dynamic and evolving participant in the IR process, designing IR systems that are adaptable and personalizable, while an increasing number of user-centered studies in the field of LIS have attempted to draw design implications from their findings. This entry has addressed the main efforts made by both research communities so far to bridge the gap, in terms of theoretical models, system designs, and ever evolving evaluation metrics and methodologies. In the future, it can be fully expected that the overall research stream will flourish with

the emphasis on human-computer interaction as the means, as well as the goal of effective and efficient information searches as the end.

ACKNOWLEDGMENT

The author would like to express gratitude to Dr. Ping Zhang at Syracuse University, whose valuable suggestions helped shape this entry, and to Dr. Marcia Bates at University of California, Los Angeles, who has generously helped edit this entry.

Humanities Literatures and Their Users

Stephen E. Wiberley, Jr.

University of Illinois at Chicago, Chicago, Illinois, U.S.A.

Abstract

This entry discusses definition of the humanities, reviews briefly the history of study of uses of information in the humanities, presents the characteristics of different types of literature used in humanistic scholarship in various fields, outlines how scholars identify and access different types of literature, and discusses the use of digital information by humanities scholars.

INTRODUCTION

This entry has five goals. First, the entry aims to show the range of approaches toward definition of the humanities. Most relevant to library and information science (LIS) is a definition that distinguishes the humanities from the sciences and social sciences in terms of the sources of information that provide humanists with their basic evidence. Second, the entry gives a very brief history of the study of use of different types of literature in the humanities. Third, the entry explains what primary literature is, its importance for humanistic scholarship, and how humanists identify and locate the primary literature they use. Fourth, the entry explains what secondary literature is, its importance for humanistic scholarship, the distinguishing characteristics of the secondary literature of the humanities, and how humanists identify and locate the secondary literature they use. The discussions of identification and location of primary and secondary literature review what is known about how humanists use access services (sometimes called tertiary literature) and consult with archivists and librarians as they seek relevant literature. Finally, the entry talks about where information seeking and use fit into the workflow of humanities scholars.

At several places, the entry refers to the use of digital literature and access services in the humanities. Until recently digital information has played a limited role in the humanities. This is likely because only a small portion of primary and secondary literature for humanities scholarship was available in digital form. The entry asserts that, now that a substantial and expanding body of literature is available in digital form, the major challenge for future research about humanities users and their literatures will be charting growth in use of digital sources and the ways in which use of them affects the conduct of humanities scholarship.

DEFINITION OF THE HUMANITIES

Approaches toward definition of the term “the humanities” vary. First, many do not define the term, but list disciplines

they think constitute the humanities. The most influential example of this approach is the legislation that established the National Endowment for the Humanities in 1965. This law asserted

The term ‘humanities’ includes, but is not limited to, the study of the following: language, both modern and classical; linguistics; literature; history; jurisprudence; philosophy; archaeology; comparative religion; ethics; the history, criticism and theory of the arts; those aspects of social sciences which have humanistic content and employ humanistic methods; and the study and application of the humanities to the human environment with particular attention to reflecting our diverse heritage, traditions, and history and to the relevance of the humanities to the current conditions of national life.^[1]

Others assert the humanities cannot be defined, but only characterized. In LIS, an influential example of this approach is Allen who states “the nature of the humanities is better understood through observation of their characteristics than by reading definitions.” She finds the humanities have

concern for the individual and for the thoughts, imagination, achievement, creativity, performance, and impact of individuals. There is a concern for culture and for all kinds of human behaviors that produce cultural artifacts. And perhaps all these concerns are framed by the larger concern for values, for quality, and for expression (p. xi).^[2]

Finally, some do define the term. In LIS, an important instance of this approach is Blazek and Aversa’s *The Humanities* (2000) that follows the Commission on the Humanities and defines the humanities as “those fields of scholarship and study that are ‘dedicated to the disciplined development of verbal, perceptual, and imaginative skills needed to understand experience.’” (p. 1)^[3]

Also within LIS, Wiberley and Jones have defined the humanities as those fields of scholarship that strive to reconstruct, describe, and interpret the activities and accomplishments of people by establishing and studying

documents and other artifacts created by those people. They recognize that all scholarship is a continuum from the sciences to the social sciences to the humanities. There is overlap between the social sciences and the humanities, but clear difference between the core of each area.^[4]

Following Wiberley and Jones, the present entry contrasts the humanities to the physical sciences that strive to describe and explain the world through evidence derived from observation and experimentation and the social sciences that strive to describe and explain the activities and behaviors of people through evidence developed by experiment, field work, and survey. Unlike scientists and social scientists, humanities scholars do not construct data gathering instruments (e.g., digital sensors or survey questionnaires) that shape their basic evidence and initially record it. Instead the basic evidence for humanities scholars are artifacts, including documents, that other people created.

The grounding of a definition of the humanities in sources of information makes it relevant to LIS. Tibbo, for example, followed Wiberley and Jones's definition in her discussion of user instruction for database searching in the humanities.^[5] The definition, in effect, includes most of the fields normally associated with the humanities: classics; archaeology; literary studies; and history, criticism and theory of the arts, including both fine arts and music. Nevertheless, the definition is unconventional in that it, in effect, includes most of history, often categorized as a social science, and excludes philosophy in the Anglo-American tradition and most of linguistics that are usually grouped with the humanities in universities and by funding agencies and are included in a number of LIS studies about the humanities. This entry discusses philosophy and linguistics, but its conclusion summarizes the article in relation to the Wiberley/Jones definition.

HISTORY OF STUDY OF USES OF INFORMATION IN THE HUMANITIES

In 1975, Bebout, Davis, and Oehlerts asked why there were so few user studies in the humanities, when user studies in the sciences and engineering had a long history and user studies in the social sciences were a growing interest.^[6] Four of the five studies of humanities users they referenced were citation studies. Less than a decade later, Stone, citing over 80 different sources, summarized what had been learned to that point about humanities scholars. Few of the sources Stone cited were user studies, most were informed opinion of an individual about the humanities and the work of humanities' scholars. Among the user studies were a handful of surveys from the United Kingdom and the United States.^[7] In 1994, Watson-Boone synthesized the findings from seven interview or questionnaire studies and six studies of sources used, including two studies covered by Bebout, Davis, and Oehlerts and one that Stone had reviewed.^[8]

Since 1994, researchers have conducted additional questionnaire and interview studies as well as more citation studies. Some scholars, including Bates,^[9] Cole,^[10] Cullars,^[11] Dalton,^[12] Heinzkill,^[13] Knieval and Kelsey,^[14] Palmer and Neumann,^[15] Tibbo,^[16] and Wiberley and Jones,^[17] have published multiple studies that build on their previous work. Because the most recent, relevant publications by these authors cite their earlier work and many other germane publications, this entry generally cites only their latest work.

Unlike Bebout, Davis, and Oehlert, we today know much about how humanities scholars use the literatures of their fields. At the same time, there is more to learn, both because our knowledge is incomplete and the rapid growth of digital primary and secondary literature is likely to change greatly humanities scholarship. Among other things, we need to learn about the predominant types of humanities scholarship so that information professionals can understand humanists better and serve them more effectively.

TYPES OF LITERATURE USED IN THE HUMANITIES

This entry is about the literatures of the humanities. By literature is meant written sources, usually called documents. The social sciences and the sciences have two kinds of literature. First, there is the literature in which social scientists and scientists write about the results of their scholarship. Second, there is a literature that describes and indexes the publications written by social scientists and scientists. This second kind of literature is often called access services. For scholarship in the humanities there are three kinds of literature: primary literature that contains the evidence on which humanists base their scholarship, secondary literature in which humanists write up their scholarship, and access services that describe and index the publications written by humanists. This entry will focus on the primary and secondary literature because there has been substantial research about use of them. It will discuss access literature in relation to them.

Use of primary sources is essential for any work in the humanities. Use of secondary literature is not essential. For example, some significant twentieth century literary criticism cited no secondary sources. But today, the more one aspires for expertise and recognition in the humanities, the more one must engage and cite the secondary literature.

Primary Literature

The primary literature is that which is written by the persons whose activities and accomplishments the humanist seeks to describe or interpret or by persons who observed first-hand the subject whose activities and

accomplishments the humanist studies. For a study of George Washington during his presidential years, the following are examples of primary literature a humanities scholar might use: the correspondence of Washington, his family, friends, political allies, and opponents, and diaries, newspapers, and magazines from his era. For a study of Mark Twain's *Huckleberry Finn*, primary literature could include editions of the novel prepared with the author's participation, Twain's notebooks and correspondence, the papers of the novel's publisher, the records of the persons who manufactured copies of it, and publications and personal papers that contained responses to it.

There are a variety of perspectives for analyzing and classifying sources that can be considered primary literature. Does the source exist only in its original version or are there later versions of the source? Was the source unpublished, that is, created only for personal use or limited, controlled distribution or was the source published, that is, purposely disseminated to the public through established channels of distribution? Does only one copy or do many copies survive? Is the source in the possession of an individual or in an institutional collection? If in an institutional collection, is the collection organized as an archive or as a library? In what medium does the source exist: paper, microform, or digital?

Each of the characteristics of primary literature outlined above affects use. Generally speaking, the more public a source, the easier it is for people to use that source. That is, if a source was initially published in many copies (e.g., a popular novel), it is more likely to be available than if it has only existed in one copy that was made for personal use (e.g., a letter to a friend). Similarly, if a source is in a publicly accessible repository, it is easier to locate and use than if it is in private hands.

While there are numerous cases of scholars using primary sources from private, including personal, collections, for the most part humanists use sources held in institutions—libraries, archives, and museums. This is especially true of older sources in original format. As time passes, few artifacts survive for scholars' use unless they are under institutional care.

Primary literature also includes the digital file of a document. An interesting question is whether a digital file is in itself primary literature or its display on a screen or in print is primary literature. The characteristics that make it primary literature are not apparent until they are displayed, yet without the stored file their appearance is impossible.

Extent of use of primary literature

The landmark work of Cullars on citation patterns in humanities monographs is the best starting point for learning about the extent of use of primary sources in humanities scholarship. Cullars's research and his review of other studies tell us that approximately half of all references in

humanities scholarship are to primary sources. In fine arts scholarship, references to primary literature range from 30% to 45% of all references. When references to art objects (also primary sources) are added to references to primary literature, the percentage ranges from slightly less than 50% to more than 60%. In investigations of studies of literature in western European languages, Cullars found that the percentage of primary literature cited ranged from 49% to 61%.^[18] Other research has found that citations to primary sources are normally more than half of all citations.^[12,13] Interestingly, Cullars's discussion of characteristics of citations in philosophy questions the applicability of the distinction between primary and secondary sources for that discipline because essentially all philosophical writing interprets other philosophical writing. He finds that it is impossible to make a distinction between teachers (in other humanities disciplines the authors of secondary sources, e.g., literary critics) and practitioners (in other disciplines the authors of primary sources, e.g., novelists).^[11]

Access to primary literature

How do humanities scholars gain access to the primary literature that they use? Normally to gain access a person first has to identify a given source as relevant and then locate a copy. Sometimes location comes first and then identification follows. For example, location precedes identification in browsing of book stacks.

Presuming the normal sequence of identification preceding location, we can ask how identification occurs. This question has two parts. First, what terminology do humanities scholars use when they seek primary literature? Second, what sources do humanities scholars use when they seek primary literature?

Regarding terminology, the Getty End-User Online Searching Project showed that humanists distinguish themselves from scientists and social scientists by using proper terms in their information seeking.^[19] Proper terms include names of people (Charles Dickens), places (London), and time periods (Victorian Era). While the Getty study was about retrieval of secondary literature, its findings about use of proper terms apply to primary sources. Reports about users of archives and manuscript collections also tell us that they use names of people and organizations to find relevant sources. In addition, the evidence indicates that humanities scholars use proper terms to organize their notes and to build their understanding of their topics.^[10,20] Humanities scholars do use common terms in their searching, but when they have a topic that lends itself to being described or pursued with proper terms, they use them.

There are several means that humanities scholars use to locate primary literature. For primary literature in archives and manuscript collections, Tibbo's survey of historians in 2001 is the most informative study about historians'

self-reported approaches to archival materials at the turn of the century. First, almost all scholars, at some time, identify relevant collections through leads and citations in printed books and articles. Roughly four-fifths use printed bibliographies, finding aids, and repository guides as well as their home institution's online catalog. Approximately three-fifths search other institutions' online catalogs and bibliographic utilities like OCLC (Online Computer Library Center), and visit repository Web sites. About two-fifths use Web search engines. Younger historians tend to use electronic means more than older historians. Because an increasing number of finding aids and archival documents are appearing on the Web, it will be important to chart change in use of electronic means of identifying relevant collections. Scholars also consult curators and colleagues to find needed materials. Approximately four-fifths ask colleagues, and most ask repository personnel for assistance whether by writing, telephoning, or e-mailing.^[16]

Once at the archives, scholars make great use of finding aids.^[12,16,20] Finding aids describe the individual or corporate body that created or gathered the records, and they enumerate, usually at the folder but sometimes at the document level, the collection's components. While at the archives, scholars also seek help of curators. Because archive and manuscript collections contain unique materials that are not described and cataloged in standardized ways as are books and journals, they are not as easy to find. Interviews with scholars who use archives and manuscripts reveal that most report enlisting the help of collection curators to tell them of recent acquisitions not yet processed, to identify collections the scholar has not found by other means, and to pinpoint relevant materials within collections that the scholar has identified as relevant but not yet examined.^[20]

By no means are all primary sources found in archives and manuscript collections. Literary critics or theorists, for instance, may never use an archival source. For many topics, most relevant primary literature was published. Published literature may include books, magazines, newspapers, and government publications. It also includes modern scholarly editions of older sources, for example, the University of California Press edition of the works of Mark Twain and the University Press of Virginia edition of the papers of George Washington. To locate published sources, use of library catalogs—ranging from the global WorldCat to the local catalog—is essential.^[12]

It should be noted that scholarly editions are an important exception to the general rule that humanists do not contribute to the development of their basic evidence. In scholarly editing, editors make choices, sometimes numerous and sometimes debatable, that shape the content of the scholarly edition. To be sure, editors must be faithful to the content of the original primary literature that initially recorded the basic evidence and must have evidence to justify changes they make. Nevertheless, scholarly

editions differ, even if slightly, from manuscript correspondence, first editions of novels and the like on which they are based.

Digital primary literature

Since the 1980s, studies of humanities scholars have explored the role of digital primary literature in their work. In general, these studies found that few scholars used digital sources and those who did were usually at the margins of their disciplines. This led to the claim that humanities scholars were intrinsically not just opposed to digital sources, but to information technology. Research, however, has shown that, in general, humanists adopt information technology whenever it benefits their work. Most important, the limited use of digital literature appears to have been a function of the scarcity of sources in that format.

The case of ancient Greek texts is instructive in this regard. Since the mid-1980s, the *Thesaurus Linguae Graecae* (TLG) has made available a vast digitized dataset of those texts. Once available, these were used widely by classicists.^[21] The advantage that classics had was that Greek primary literature was limited in scope and much of it could be digitized with the given technology available at the time. For many years, other fields, where the potential primary literature was vast or innumerable, were not in a position to launch such a conversion.

In the present century, the availability of digitized primary literature has grown enormously, largely driven by commercial firms that convert microfilmed sources into digital form or digitize books from partner libraries' collections. Presumably use of these digitized sources is following. A major challenge and obligation for future research about the use of primary literature by humanities scholars is to chart the growth in use of digital literature and how that growth changes use of information and humanities scholarship. To give a simple example of how scholarship might change, we can consider that traditionally historians have identified relevant passages in archival sources by what Cole aptly calls "scan reading."^[10] With computers, scholars can have the machine identify relevant passages either by simple keyword matching or more sophisticated software analysis. Traditionally, scholars have debated each other's judgment and thoroughness in examining the primary literature. In the future, debate may center on choice of keywords or on software selected to screen primary literature.

Because primary literature, often in its original state, is important for humanities scholarship, the preservation of born-digital sources is essential. So far there is no demonstrated ability to preserve digital information over the long-term as well as we can preserve print-on-paper information. Even the most basic forms of documents, for example, e-mails and word-processed letters or drafts of literary works, are at risk. Beyond the fundamental need to

preserve the character strings, it is highly desirable, in some cases at least, to preserve digital information so that it has the same appearance as in its original state. Preservation of the original look of a text may prove extraordinarily difficult, if not impossible. An important question is whether future humanities scholars will be able to analyze the appearance of decades-old, born-digital literature, the way their predecessors analyzed the layout and typography of literature from the print era.

Secondary Literature

In the humanities, secondary literature is writing that describes or interprets what people, usually scholars, find or conclude when they study primary sources about the activities and accomplishments of other people. A book about Washington's presidency and an article in a literary journal about *Huckleberry Finn* are examples of secondary literature. One distinctive characteristic of secondary literature in the humanities is that it normally is the work of a single author. In much of the social sciences and most of the sciences, coauthorship is the norm. Single authorship does not mean that humanities scholars never interact with other scholars. In fact, they normally consult colleagues as well as information professionals. But they do more of their work in isolation than scientists and social scientists.

Also noteworthy about the secondary literature of the humanities is the possibility that it can become primary literature. For instance, scholars may study the evaluation that other scholars have given to Washington's presidency over the years, or they may study critical reaction to *Huckleberry Finn* during different eras. In these cases, books about Washington's presidency or journal articles that interpret *Huckleberry Finn* become primary literature.

A portion of the secondary literature that humanities scholars use is published during their careers. As a result, given natural patterns of book purchase and journal subscription, scholars often use personal copies of secondary literature. For many humanists, use of personal copies of secondary literature contrasts with use of primary literature that is often available only in repositories. At the same time, topical and temporal scatter of secondary literature is normally so great in the humanities that few humanists will own more than a fraction of the secondary sources they use and will rely on libraries for the rest.

Format

In the humanities, the formats in which scholars publish their research are books and journals. Most books are monographs by a single author about a single topic, but a small percentage is books that contain chapters by different authors. Research about formats cited in humanities publications has almost always reported the percentages of books without differentiating between

those single-authored and those with different chapter authors. Also, almost all reports about format are separate from reports about proportions of primary and secondary sources, so there is little to say about the proportions of primary and secondary sources among books and journals. As a result, a synthesis of citation studies cannot present a detailed picture. Despite difficulties in generalization, one trend seems clear. Scholars today cite more literature than their predecessors.^[12,22]

While most research has not differentiated between format of primary and secondary literature, two studies of citations to secondary literature have found that about 75% to 80% of those citations were to books and 20% to 25% to journals.^[12,14] Interestingly, these percentages for books and journals also hold with small variations when citations to primary and secondary literature are combined.^[8,11,13] Linguistics appears not to fit this pattern. In linguistics, studies have found books to be 50% to 60% of citations and journals 40% to 50%.^[14,23]

Age

Humanities scholars are noted for the age of the literature that they use. While in many scientific and social scientific fields it is unusual to cite literature that is more than 10 years old; in the humanities, it is normal to cite literature that is more than a decade old or older. How much of this difference in age of sources is attributable to secondary sources is impossible to say because citation studies in the humanities have not differentiated age of primary sources from age of secondary sources. Furthermore, because different studies use different time frames to report their findings, we can only generalize broadly about their results. That said, the available data are worth presenting, if only to reinforce the overall difference in the use of literature by humanities scholars from the use of literature by scientists and social scientists. Watson-Boone's summary of eight studies shows that roughly one-third of sources cited or used are more than 30 years old.^[8] Later research supports this generalization, except for linguistics.^[11,13,18] In linguistics, almost 90% of the citations are to publications less than 30 years old.^[14,23]

Language

Increasingly after World War II, English became the language of science and today most of the important scientific publications are in that language. The social sciences are less tied to English, but many important international journals are in that language. In the humanities, non-English language publications remain important. As with age, some of the difference stems from citations to primary literature. Nevertheless, Knieval and Kellsey's study of citations to secondary sources in English-language journals in eight humanities disciplines found that the percentage of non-English language publications cited

ranged from one-sixth to one-third, except for linguistics (10%) and philosophy (1%).^[14] Other research supports the finding for linguistics, but not philosophy.^[11,23] Topic of study and the language of a study's author affect language of sources cited. Thirty percent of citations in a sample of English-language monographs in fine arts that included titles about artists from non-English speaking countries were to non-English language publications. German and French fine arts monographs cited their native language about 70% of the time.^[18] In English-language journals about English and American literature nearly 100% of the sources cited were in English.^[13]

Identifying and locating secondary literature

While there are few studies of the use of bibliographic databases like *Historical Abstracts* or the *Modern Language Association International Bibliography* by humanities scholars, evidence indicates that these databases are used more today than their print counterparts were in the past. Dalton and Charnigo found that in 2003 historians preferred bibliographic databases more than other means to identify secondary literature relevant to their research. This contrasts with Dalton's 1981 survey that found abstracts or indexes ranked fifth among means to identify relevant secondary sources.^[12] Increased reliance on bibliographic databases makes sense given that they are easier to use than print indexes—searching of the entire database can be done at the scholar's desktop, eliminating a trip to the library and a series of lookups in separate index volumes—and given the growth in the literature with which scholars must cope.

Besides using bibliographic databases, scholars employ traditional methods of following references in publications they read, looking at specialized bibliographies (e.g., one about the American revolutionary war), searching library catalogs, and reading book reviews and listings of new books and journals. To a lesser extent, scholars consult colleagues and other experts, and, to a slightly lesser extent, librarians. Interestingly, online discussion forums of various sorts seem to have almost no value for identifying secondary literature.^[12]

The previously mentioned Getty End-User Online Searching Project showed that when searching for secondary literature in bibliographic databases, humanists use proper nouns much more than scientists and social scientists. The Getty researchers compared queries of humanists whom they studied with queries of scientists and social scientists found in a study by Saracevic and Kantor. Only 18% of the science and social science queries used proper terms, while 84% of the humanities queries did. Among proper terms, nearly 50% of the humanities queries used the names of individuals. From the perspective of common terms, 100% of the science and social science queries used common terms, while only 57% of the humanities statements did.^[19]

Digital secondary literature

During the past 10 years, more and more of the secondary literature of the humanities has become available in digital format. Major university presses have begun to release digital copies of their books, and humanities journals are increasingly available over the Web. How humanities scholars are using digital secondary literature needs investigation. The book is the most important format for humanists, yet the length of books makes it difficult to read them on screen and impractical to print them out. After scholars discover online relevant books, they may obtain printed copies for reading by purchase or borrowing from a library. Because journal articles are shorter than books, online versions may be what all libraries need to acquire. Scholars who do not read journal articles on-screen can print them out for reading. Even if scholars read only the digital version of a book or journal, they likely will find it easier to cite those articles in traditional form without their URLs. Thus citation data may not necessarily tell what format of a publication the scholar actually used. Survey research will be necessary, while recognizing that what people say they do does not necessarily correspond to their behavior. Important too will be learning if there is a difference between use of digital primary literature and use of digital secondary literature. One hypothesis to test is that humanists use computers to identify relevant passages of primary literature and then read only these passages, but read through secondary sources and use information technology only to deliver the source, not parse it.

How humanities scholars integrate information into their work

Thus far this entry has discussed use of the literatures of the humanities from the perspective of the literatures themselves, both primary and secondary, characteristics of those literatures, mechanisms of access, and digital formats.

Another way to discuss literatures is in terms of how they fit into the scholar's workflow. At what points in a project do humanities scholars normally seek primary and secondary literatures? When do they read those literatures? For literary critics, Chu has proposed a model and noted common variants to it. Not surprisingly, the greatest concentration of searching for primary and secondary literatures occurs after the scholar decides to pursue a topic and before the scholar drafts the write-up. Between those two points, the scholar reads the sources that the search has identified. For some projects of mature scholars, there is no initial search to identify relevant primary and secondary literature, because the scholar already knows what they are. Nevertheless, in all cases, whether the topic is new or familiar, analysis and writing reveal that the scholar needs slight to moderate amounts of additional information and this revelation leads to searching for that information and reading of the sources identified by the search. An important

difference between literary critics, on the one hand, and scientists and social scientists on the other, is that literary critics do not spend time constructing data gathering instruments to record initially their basic evidence. Construction of instruments for initial data recording is unnecessary in the humanities because that evidence already exists.^[24]

Other research by Case on how historians work concludes that “stages of research are illusory” and that “choosing and refining topics, planning and conducting studies, gathering and interpreting evidence, and writing and revising manuscripts can go on concurrently, both within and across individual projects.”^[25] It may be that humanists, like Chu’s literary critics, who begin with an interest in specific works of art, literature, and music and then study those works differ from humanists, like Case’s historians, who begin with topics and then explore bodies of archival materials and other blocks of primary sources like newspapers in order to understand those topics. The projects of the latter group of humanists are usually more open ended than those of the former group necessitating more iterations of seeking additional information, refining the topic, and revising the write-up.

Exposition of the elements of the workflow of humanities scholars is an important advance in our understanding of their use of information. With models in mind, practitioners can be more sensitive to the needs of humanists with whom they work. For example, while identifying a long list of relevant literature can help a humanist at the start of a project, a long list probably will be a hindrance after the analysis and writing stage when the humanist is addressing specific information needs.

There is still much to learn about how humanists use information for different types of scholarship. Tibbo, for example, found that social historians differ from biographers in the ways they seek information about archival collections.^[16] We know that critical and documentary editions differ from publications of interpretative types of humanities scholarship like criticism, history, and theory. But we lack analyses of the nature of these and other differences, their relationships to searching for and use of primary and secondary literatures, and their meaning for practice by information professionals. This is a challenge because to understand well humanities scholarship, one must study both scholars in many disciplines and books that are far more difficult to analyze than journal articles. The greater availability of digital versions of books should help in this regard, because it provides machine-readable data for such analyses.

CONCLUSION

The literatures of the humanities and the uses of them have several characteristics that distinguish them from the literatures of the sciences and the social sciences and use of those literatures. While the sciences have as their basic evidence results of observation and experiment and the

social sciences the results of experiment, field work, and survey, the humanities study artifacts, especially documents, created by other people. The documents that are the humanist’s basic evidence constitute the primary literature of the humanities. Scientists and social scientists do not have a comparable literature. Almost half of the citations in humanities scholars’ publications are to primary literature or other primary sources. Because the humanities study what people have done in different places and at different times, proper terms, especially the names of individuals, are very important in retrieval of literature, both primary and secondary. Also, because humanities scholarship builds upon documents and artifacts created by different people in different places and times and not by the humanist who uses them, there is less possibility for conventions of method or uniformity in procedure in humanities scholarship than there is in the sciences and social sciences where scholars themselves initially record their basic data. Without a role in the initial recording of their basic data, humanists are less able to construct paradigms than are scientists and social scientists. One consequence of uniqueness of setting and basic evidence and the lack of paradigms and conventions of method is that publications in the humanities generally have to be longer than those in the sciences and social sciences in order to explain the context of the findings and the way in which the scholar developed them. As a result, the book, rather than the journal article, is the predominant form of publication. Lacking paradigms and conventions of method, humanities publications do not build on a sequence of preceding scholarship as easily as do the sciences and social sciences, and so are less likely to cite new scholarship than scientific or social scientific publications. Given that they discuss past activities and accomplishments in different places around the world, there is greater diversity in language of sources cited in the humanities publications than in scientific and social scientific publications.

Because humanists generally do not have a role in the development of their basic evidence as do scientists and social scientists, they have applied more slowly information technology to their scholarship. Since the turn of the century, the availability of digital primary literature has increased very significantly, as countless documents are born digital and innumerable paper-based sources are converted into digital form. Increased digitization of primary evidence and secondary literature is likely to change greatly humanities scholarship. Today, the primary task for research about use of literatures in the humanities is to study effects of this digitization on humanities scholarship.

Abstract

After briefly introducing the history of Hungarian literacy, libraries, publishing, record keeping, and museums, this entry gives an overview of Hungarian libraries, the discipline of information science, and the library and information profession, including education for library professionals, and professional associations in the country. A similar review follows about archives: an overview of the different kinds of archives, archival science, education for archivists, and the issue of electronic records. The last section of this entry describes the various kinds of museums, museology, education for curatorship, and professional associations in Hungary.

INTRODUCTION

Historical Context

Hungary is a country in Central-Eastern Europe. 10.3 million inhabitants live in a territory of 35,907 miles² (93,000 km²) (see Fig. 1). The capital is Budapest. Its official language is Hungarian, a Finno-Ougric language. The Hungarian alphabet consists of Latin with the addition of diacritics and two or three letter combinations in order to cover the characteristics of Hungarian phonemes.

The history of literacy and the currently used Latin alphabet is 1000 years old: it goes back to the years after 1000 A.D. when the Hungarian state was established. István I (Stephan I, 1001–1038) Christianized the formerly tribal and pagan people that had used a special type of cuneiform as their writing system. Literature had been orally transmitted during the nomadic period, with written literature appearing shortly after 1000. István I founded monasteries that fulfilled not only religious but also educational functions. Most of the early monasteries probably had libraries holding handwritten literature for ecclesiastic purposes. The most famous was the monastery and library of Pannonhalma, founded in 1001, that operated the first school of the country. An inventory from 1093 indicates the ownership of 80 books. Very little from the early monastic library holdings remained as they were all destroyed during the Mongol invasion (1241).

Early texts as well as the official documents of the royal court were written in Latin. Charters recorded medieval land transactions from the turn of the eleventh century onward. Béla IV (1235–1270) ordered the compulsory recording of land transactions and other legal acts. Systematic tracking of regal decrees (Regestrum) started from 1308 on. The earliest extant Hungarian text is a funeral sermon, “Halotti Beszéd,” which has been found in the Latin *Pray Codex*, a work from 1192.

The first universities were founded in the second half of the fourteenth century in Pécs (1367) and Ó-Buda (1387), but were closed during the Turkish occupation of the country (1541–1699). The earliest predecessor of the current universities was founded by the Catholic Church during the first half of the seventeenth century in Nagyszombat (now Trnava, Slovakia) where the Esztergom Archbishopric moved from the territory occupied by the Turks.

Book culture was restricted to the church until the end of the fourteenth century, but extended to secular areas during the Humanist Movement of the fourteenth and fifteenth centuries when lay people began to collect books and build small libraries. The first printed book written in Hungarian dates from the first half of the fifteenth century.

The great Humanist ruler Matthias Corvinus (Corvina Mátyás, 1458–1490) represented the high point of early book culture. Matthias’ library, the *Corvinae*, included 2000–2500 mainly handwritten illustrated codices in Greek and Latin, their topics ranging from physics and mathematics to philosophy. Most of these books, created by some of the famous Italian workshops, were richly illustrated, decorated with gold, and individualized by Matthias’ coat of arms. The library was open to those who needed to use the books, particularly scholars, many of them visiting Hungary because of the library itself. Only 216 pieces of this famous collection remain: 52 in Hungarian libraries, the rest in the libraries of 43 different cities in 16 different countries. Rulers succeeding Matthias were not interested in preserving or developing his library, and the collection was given away; what remained was destroyed during the Turkish occupation of the country.^[1]

Andras Hess founded and operated the first printing press in Buda in 1473, during the reign of King Matthias. The workshop’s first product was a book entitled *Chronicle of Buda (Chronicon Budense)*. This press closed after a few years, and Hungarian books were printed abroad for almost a half century.

Fig. 1 Map of Hungary.

Source: CIA World Factbook.^[59]

During the Turkish occupation (1526–1699) of a large part of Hungary's territory, book culture and the Humanist Movement continued in the territory held by Austria and in Transylvania. Printing presses were established in these territories rather than in Hungary because the Sultan officially forbade the printing of books in occupied land.

Government documents of the Hungarian Kingdom were systematically archived from 1613 on, but the documents stayed in private property, and were sometimes destroyed or distributed by the heirs until 1723 when a law ordered their deposition in specific governmental archives.

The foundation of the first university (Nagyszombat) and Catholic and Protestant colleges (Debrecen, Sárospatak, Pápa) from the mid-sixteenth century on paralleled the establishment and development of new libraries. Book printing spread all over the country; important Catholic printing firms operated in Vienna, Pozsony (now Bratislava, Slovakia), and Nagyszombat. The most important figure of early Hungarian book printing, *Misztótfalusi Kis Miklós* (1650–1702), studied in Amsterdam in the workshop of the Bleau family and published more than 100 books, the most famous of which was the *Golden Bible* (*Aranyos Biblia*, 1685). The Reformation gained momentum and had a positive effect on the diffusion of the use of Hungarian language and printing. Protestant printing presses were established in Debrecen, Pápa, and Eperjes (now Presov, Slovakia). The first Hungarian journal, *Magyar Hirmondó*, was started in 1780 in Pozsony.

Building library collections in richly furnished library rooms became fashionable among high-level aristocrats

and clergymen during the seventeenth and eighteenth centuries. The Festetics Library in Keszthely has been preserved in its wonderful original state as has the Teleki Family's library in Marosvásárhely (now Târgu-Mureș, Romania).^[2]

The spirit of Romanticism and the emergence of national consciousness generated an increased interest in language standardization and the establishment of a broad range of new institutions, among them the Hungarian Academy of Sciences (*Magyar Tudományos Akadémia*), the Budapest University Library (*Egyetemi Könyvtár*), and other libraries, archives, and museums. The most important among them was the Hungarian National Museum and Library (*Magyar Nemzeti Múzeum és Könyvtár*), created in 1802 by count Ferenc Széchenyi who donated to the new institution his library, his collections of coins and sculptures, as well as other valuable objects. A law proclaimed the foundation in 1807. The current building of the museum, planned by architect *Mihály Pollack*, was completed in 1846. Before the close of the century, several new museums emerged from the collections of the National Museum. The current Museum of Science (*Természettudományi Múzeum*) grew out of a large collection of minerals donated by Ferenc Széchenyi's wife. The Ethnographic Museum (*Néprajzi Múzeum*) split from the National Museum at a later date. The second part of the nineteenth century saw the foundation of a series of new museums (Museum of Applied Art, *Iparművészeti Múzeum*; Museum of Fine Arts, *Szépművészeti Múzeum*, the Zoo, etc.) due mainly to the enhanced economic

conditions after 1867 and the activity of a few great scholar-managers, e.g., *Ferenc Pulszky*, *Flóris Römer*, *Károly Pulszky*, and *György Ráth*.^[3] Libraries and museums have been overseen together by the Main Supervisory Office of Museums and Libraries since the end of the nineteenth century. The main goal of this cosupervision was to increase cooperation between the two types of institutions. This governmental office started the first periodical of the two fields, the *Múzeumi és könyvtári értesítő* (Museum and Library Bulletin) in 1907.

A nationwide effort to standardize the national language began in the second half of the eighteenth century; in this era, the greatest writers and poets created those linguistic forms that effectively determined classical national literature and language. In 1844, Hungarian became official language of Hungary instead of Latin; official documents had to be composed in the national language from this time on. Compulsory sixth grade education begun in 1868.

Formerly, Hungary's governmental documents had been written in Latin and had been collected and stored together with Austria's governmental documents in the *Haus-, Hof- und Staatsarchiv* of the Austro-Hungarian Monarchy since 1749. In 1756, however, a separate archive was created for holding the governmental documents of Hungary, now part of the Habsburg empire. The Palatine, lieutenant-governor of the emperor, exercised supervision over its operations; he was responsible for collecting, preserving, and passing along the documents to the office of the next Palatine.

Independence from Austria, the main goal of the 1848 revolution, failed but a few decades later, the Compromise (Kiegyezés, 1867) established a dual state structure and numerous measures that assured partial independence, self-government, and economic growth. Among many other changes, the Palatine's Archive (*Archivum Palatinum*) was transformed into *National Archives* (Országos Levéltár), signifying the relative independence of Hungary from Austria. A renowned historian, *Gyula Pauler* was appointed chief archivist; he introduced new regulations that permitted scholarly research in the institution. The new Archive took over the documents of the feudal governmental institutions and juridical courts collected by its predecessors. More appropriate space for this immense set of historical holdings was built and opened in 1923. This building still houses the Archives and is located at the southern entrance of the castle area in Budapest.^[4]

Citizens and families were allowed to deposit their own private documents in a different archive that was part of the National Museum and Library; this archive later split off from the parent institution, and became independent under the name Museum-Archives (*Múzeumi Archivum*) in 1926 until its ultimate merger with the National Archives (*Országos Levéltár*) around 1934.

Book printing became an important industry in the nineteenth century when several technologically advanced

printing companies were established together with major editorial firms (*Franklin, Athaeneum*). *Izidor Kner* and *Andor Tevan* were the most outstanding representatives of artisan bookmaking. Popular demand for broader ranges of books resulted in the opening of public libraries; the first among them was the *Fővárosi Könyvtár* (Library of the Capital), opened in 1904 by *Ervin Szabó*, a social scientist-librarian, who successfully convinced book producers and traders that public libraries will not ruin the flourishing book industry. He established a large network of public libraries in the capital based on the Anglo-American model; its book circulation in 1914 was 190,000 volumes.

During the interwar period, Hungarian libraries—with a few exceptions—were in decline due to insufficient funding. The only library that made some progress was the National Széchényi Library where special collections were enhanced by the return of 16 Corvina codices, the Picture Chronicle, and the *Gesta Hungarorum* among other texts from the Habsburg Court Library of Vienna. The National Library developed its classification system as well by abandoning the Munich subject system for the Universal Decimal Classification that is still the organizational principle of the books in the stacks. According to Charlotte Réthi's calculations, about 1000 academic and specialized libraries held about 11 million volumes by 1939, while the holdings of the school, public, union, and other libraries was under 1 million.^[5] During World War II, many of the libraries were destroyed, and their holdings decimated, in part by looting and confiscation.

Three general trends characterized the development of libraries, archives, and museums after 1945 when Soviet-type state socialism was introduced: the radical nationalization of private institutions, the ambitious creation of village and union libraries, and the centralization of management. Library and museum collections that had been confiscated from private institutions, except a portion of those belonging to the Church, were either added to the holdings of the National Library of state-owned museums, destroyed, or distributed among other libraries. County and municipal archives were taken over by the state. Central managerial organizations were created: the National Library Center (*Országos Könyvtári Központ*) and the National Center of Archives (*Levéltárak Országos Központja*). The Central Economic Archives (*Központi Gazdasági Archivum*) was created to collect documents of the nationalized firms, factories, and other economic units, and the National Museum Center (*Országos Múzeumi Központ*) was developed to govern every single institution on the basis of 5 year plans. This structure only changed in 1968 when municipal and metropolitan libraries were again subordinated to the municipalities. According to Charlotte Réthi, the number of libraries skyrocketed: almost 10,000 libraries operated around 1953, holding more than 27 million volumes, circulating about 8 million, and serving 1.2 million users.^[6] (Works

by Madas and Monok,^[7] Blazovich and Müller,^[8] Dóka,^[9] Varjas,^[10] and Kent and Lancour^[11] are consulted on the history of literacy, book publishing, libraries, archives, and museums.)

State socialism collapsed in 1989–1990 as capitalism and democracy gained momentum. Previously confiscated holdings whose former owners could be identified were returned to church libraries, archives, and museums. Private individuals founded art galleries and other institutions, and hidden private art collections became known. On the other hand, most of the small union libraries and hospital libraries have been shut down.

Some of the archives experienced unprecedented numbers of clients requesting documents in support of restitution requests for the Shoah, prisoners of war, victims of expulsion, those turned in to the secret police, and so on. Within 4 years, almost 2 million people turned to the Hungarian archives. A number of new laws were passed about the freedom of information and the operation of archives, libraries, museums, and historical monuments. An unparalleled effort to overcome technological backwardness began: computerization and automation accelerated due to the disappearance of internal (ideological, financial) and external (trade embargo) obstacles. By 2005, 25% of Hungarian households had an Internet connection, about half of the average found in the 15 most developed European Union countries. This technological level has facilitated Hungarians' access to the growing number of digital library, archive, and museum collections and services.

From 2001–2005, the number of registered library users in Hungary grew by 19%, a feat hailed by the library profession and government authorities as an achievement in an era when libraries now compete with the Internet. The number of computer terminals in libraries grew by 47% during that same period, raising the proportion of libraries equipped with computers to 52.9%. The biggest change has been a 145% rise in interlibrary loan/document delivery transactions, contributing to more equal access to library holdings across the Hungarian population. The number of items checked out and the number of items read in the libraries themselves has remained the same—a tendency that experts interpret as a shift in the user behavior, i.e., users are turning more and more to electronic resources instead of the print.^[12]

LIBRARY AND INFORMATION PROFESSIONS, SYSTEMS, AND SERVICES^[13]

Overview of Legislation

The rights to intellectual freedom and free access to information are declared in the Constitution: “In the Republic of Hungary everyone has the right to the free declaration of his views and opinions, and has the right of access to

information of public interest, and also the freedom to disseminate such information.”^[14]

The law that specifically regulates Hungarian libraries is part of a larger legal document: the 1997 CXL Law on the Protection of Cultural Heritage, Museums, Public Libraries, and Continuing Education.^[15] The section about libraries guarantees Hungarian citizens' rights as library users, and regulates the operation and development of “libraries open to all users” (a concept broader than “public libraries”). As defined in the law, the following are “libraries open to all users”: the National Library (*Országos Széchényi Könyvtár*), local municipal libraries, county libraries, the libraries of state universities, and 11 national specialized research libraries and documentary centers listed in the appendix as the National Technical Information Center and Library (*Országos Műszaki Információs Központ és Könyvtár*), the National Health Policy Library (*Országos Egészségpolitikai Könyvtár*), the Library of the Hungarian Academy of Sciences (*Magyar Tudományos Akadémia Könyvtára*), the National Library and Information Center for Agriculture (*Országos Mezőgazdasági Könyvtár és Dokumentációs Központ*), the Library of the Parliament (*Országgyűlési Könyvtár*), the National Library of Foreign Literatures (*Országos Idegennyelvű Könyvtár*), National Educational Library and Museum (*Országos Pedagógiai Könyvtár és Múzeum*), the Metropolitan Ervin Szabó Library (*Fővárosi Szabó Ervin Könyvtár*), the Library and Documentation Service of the Central Statistical Office (*Központi Statisztikai Hivatal Könyvtár és Dokumentációs Szolgálat*), the Library of the Hungarian Film Institute (*Magyar Filmintézet Könyvtára*), and the Library of the Institute of Military History (*Hadtörténeti Intézet Könyvtára*).

Those institutions that have their own libraries, like churches, may request and receive the “library open to all users” status and, as a result, receive state support for their institutions if they fulfill all those requirements that the law stipulates. Libraries open to all users are cosupported by their parent institutions or local municipalities (if they have one) and the state.

The law guarantees free in-house access to library materials in these institutions. Users' names, addresses, ID numbers, and date and place of birth may be recorded. Additional services (borrowing, etc.) are available for a membership fee that is waived for persons under 16 or over 70 and for the disabled.

Libraries open to all users are required to employ professional librarians, develop their collections, and provide access to their own and other library collections. They participate in interlibrary loan activities, and supply statistical data about their operations.

An official current list of libraries open to all users is maintained by the Ministry for Education and Culture, the government agency that is responsible for the strategic development and supervision of the Hungarian library systems. Libraries listed by the Ministry receive financial

support from the state. The Minister for Culture and Education is required to assure a national network and database of library materials including a catalog of library holdings, a system of interlibrary loans, and a method of forwarding weeded/withdrawn materials to those libraries that want to add them to their collections. The law regulates the responsibilities of the national library, the academic and research libraries, and public municipal libraries and directs publishers to provide depository copies of books and periodicals. Specific sections deal with the management and financial regulation of public libraries.

Fair use is regulated in the 1999 LXXVI Copyright Law.^[16]

The 2003 XXIV “Transparent Pocket” (*“Üvegzszeb”*) Law requires public institutions to publicize the amounts and use of their public funding. Most public institutions—among them, libraries, archives, and museums—publicize the details of their budgets and spending on their Web sites.

The Ministry for Education and Culture appoints two supervisory bodies: the National Library Board (*Országos Könyvtári Kuratórium*), which oversees the operations of the national library and the Library Institute, and the Accreditation Committee of Libraries (*Könyvtári Akkreditációs Szakbizottság*) which makes accreditation decisions regarding programs for the education of librarians and library assistants.

National Library

The Hungarian Széchényi National Library (*Országos Széchényi Könyvtár*) collects, processes, and preserves the written heritage of Hungary and all documents pertaining to it. The Library’s complete collection of Hungarica (books and other documents published in Hungary, as well as publications related to Hungary or Hungarians published abroad) is available for users in all formats: parchment, paper, and electronic. The National Széchényi Library is the largest depository library for copyrighted materials published in the country. Its special collections include manuscripts, ephemera, photographs, old imprints, theatrical publications, maps, and musical scores. Hundreds of medieval codices, incunabula, and the most precious first-known Hungarian texts are held in these special collection sections. Surviving pieces of the library of King Matthias, the Corvinae, also belong to the Library’s exceptional collections.^[17]

The collections of the National Library are part of Hungary’s national cultural heritage; hence their use is regulated by the Ministry differently from the use of the materials held in other libraries. The main difference is that its holdings can be consulted only in-house; its collections are noncirculating. Unlike in other public libraries or libraries open to the general public, users have to buy a day ticket or membership card for in-house consultation of the collections.

The Hungarian National Bibliography (specific lists of published books, periodicals, maps, music scores, and recordings) is produced in the National Széchényi Library, and its most recent 5 years are available freely through the Internet. The library became the host and central agent of the Hungarian National Union Library Catalog (*MOKKA*), which currently unites the holdings of 17 large Hungarian libraries. MOKKA was founded during the 1980s and has thrived since 2002. Another database housed in the National Library, the National Document Delivery System, provides the software which is the basis for nationwide interlibrary loans.

Several special databases are being developed by the Széchényi Library: they provide access to the *Bibliographia Hungarica*, a searchable catalog of 73,000 foreign language translations of Hungarian literary authors since 1800. Currently in development is *Bibliotheca Eruditionis*, a database of 1500–1700 imprints published in the Carpathian basin. A virtual reconstruction of King Matthias’ Library, the *Bibliotheca Corviniana Digitalis*, is also in the making.

The Library Institute (*Könyvtári Intézet*), housed and operated in the National Széchényi Library, is a library and information science research center responsible for creating the national strategic plan, providing certain central services for librarians and libraries, offering courses for education, and conducting research in library and information science. One of the central concerns of the Institute’s 2003–2007 strategic plan is the coordination with and adjustment of Hungarian librarianship to the standards and requirements of the European Union.

The National Library was founded by Count Ferenc Széchényi on November 25th, 1802 with these words: “[This institution] I bestow upon for the good and benefit of my beloved country and the community for ever and irrevocably.” The foundational holdings included 13,000 printed books, more than 1200 manuscripts, hundreds of maps, coats of arms, etchings, coins, and more. The opening ceremony was held in 1803. A nationwide campaign was launched to raise the necessary funds from private citizens and other sources for its operations and maintenance. These financial resources made possible the foundation of the Hungarian National Museum, of which the National Széchényi Library was a part. Both institutions moved into the classical-style building of the National Museum in 1846–1847. The library later became independent from the museum in 1949. In 1985, the institution moved into the F building of the Royal Castle in Buda. Most of the collections—now about 7.5 million—are held in storage, but the most important works of reference, essential works in the different disciplines, and a certain part of the university textbook collections are available on the shelves of the reading rooms. General reading rooms are two floors above the entrance (on the seventh floor of the building). Special collections are located on the fifth, sixth, and seventh floors. Guided tours of the library, both

for individuals and groups, are available by appointment. The most valuable pieces from the collections are displayed in temporary exhibitions.

Academic and Research Libraries

The National Library, the *Central Library of the Lajos Kossuth University*, the libraries of the state universities, and the 11 research libraries listed in the 1997 CXL Law are the main institutions providing library materials for research in Hungary.

The most famous among them is the Library of the Hungarian Academy of Sciences (*Magyar Tudományos Akadémia Könyvtára*). The library is adjacent to the nineteenth-century neo-Renaissance central building of the Academy on the Pest (east) side of the river Danube. This institution was founded in 1836 by the donation of József Teleki's collection of 30,000 volumes, shortly after the foundation of the Academy itself in 1825 by count István Széchenyi. The library's main function has been to support research within the most important scholarly institution of the country. Its special collections currently include a world famous collection of Tibetan, Turkish, Persian, and Central Asian materials, as well as Hebraica. The central library of the Academy, holding more than 2 million volumes, collects materials on languages and literatures, classics, Oriental research, science-related policy, research management, and the history and methodology of science. Members of the broad network of research institutes of the Academy all include discipline-specific libraries collecting scholarly materials in a broad range of the sciences, social sciences, and humanities.

The National Technical Information Center and Library (*Országos Műszaki Könyvtár és Dokumentációs Központ*) collects materials and provides services in the sciences, economics, and engineering. More than 2 million items are held in the institution. The Center builds and provides access to a number of important databases, including the Hungarian Repertory of Technical and Economic Information (*Magyar Műszaki és Gazdasági Repertórium*), and the Hungarian Research and Development Abstracts (in English).

The National Library of Health (*Országos Egészségszakkönyvtár*) compiles the Hungarian Medical Bibliography and extensively collects materials related to public policy, international health organizations, and management of medical institutions.^[18–20]

The National Library and Information Center for Agriculture (*Országos Mezőgazdasági Könyvtár és Információs Központ*) compiles the Hungarian Agricultural Bibliography. Its comprehensive agricultural collections serve a broad range of academic and practical needs for professional institutions as well as the general public.

The holdings of the National Educational Library and Museum (*Országos Pedagógiai Könyvtár és Múzeum*) include a comprehensive Hungarian and selective foreign

collection of publications—monographs and periodicals—on pedagogy and its interdisciplinary fields (psychology, sociology, etc.). Its special collections include publications (yearbooks) of Hungarian schools as well as children's and youth periodicals. This institution houses the Hungarian branch of the Center to Promote Language Education in Europe, an institution of the Council of Europe helping European Union (EU) member countries to encourage excellence and innovation in foreign language teaching. This library produces the Hungarian Educational Technology Database.

The Library of the Parliament (*Országgyűlési Könyvtár*), founded around 1866, is located in the renowned nineteenth-century neo-Gothic building of the Hungarian Parliament, on the east bank of the river Danube. Its main collections focus on law, government information (as a depository library of the EU), and the social sciences (particularly political science and sociology).

The Library of the Central Statistical Office (*Központi Statisztikai Hivatal Könyvtára*), one of Europe's largest statistical collections, was founded together with the Hungarian governmental statistical service in 1867, and became a research library open to the public as of 1897. The library collects comprehensively in Hungarian and selectively in foreign materials on statistics, demography, and other social sciences, especially the economic-statistical aspects of the other social sciences.

The National Library of Foreign Literatures (*Országos Idegennyelvű Könyvtár*) is the newest from among the large Hungarian research libraries. Belles lettres—especially contemporary literature—linguistics, and music constitute the core of its collections which are primarily in English, French, German, Italian, Russian, and Spanish. This library is a research center and coordinator of public libraries serving minorities (Slovak, German, Serbian, etc.) living in Hungary. The library has borne its current name since 1989; its predecessor, the Gorky Library, founded in 1956, was a center for Russian culture.

More than 200 private- and state-funded university and college libraries served higher education and the general public in 2002.

University and college libraries demonstrate considerable strength in their print collections: the collections of the libraries of *Eötvös Loránd University* (Budapest), *Attila József University* (Szeged), and *Janus Pannonius University* (Pécs) number in the range of 3.5, 1.2, and 1.6 million volumes, respectively.

A sharp increase in the number of college students, the economic conditions of the transformation period from state socialism to capitalism and democracy, and the required merger of small specialized institutions into larger organizations brought many challenges to these libraries during the 1990s and early 2000s. These changes generated more active cooperation and resource sharing especially in the fields of digitization, delivery of online services, license negotiation, and electronic resource management.

Public Libraries

Budapest, the capital city, has its own central public library, the Metropolitan Szabó Ervin Library (*Fővárosi Szabó Ervin Könyvtár*), named after an early twentieth-century social scientist and librarian. The city also hosts a broad network of metropolitan district libraries (57 in 2007). The central library is located in the beautifully renovated building of the Wenckheim palace and extends to the neighboring Pálffy palace, home of the music collections. All 19 counties and all of the nearly 300 municipalities are required by law to operate a public library. Small settlements have to run their own public libraries if their population exceeds 2500–3000. These towns may choose to run their own libraries, or, order library services through the Service System for Rural Areas. Mobile libraries are routed to villages with fewer than 1000 inhabitants. In 2007, more than 2500 villages had their own public libraries that, in addition to supporting primary, secondary, and continuous education, information, and leisure-reading, have a special role in collecting and preserving locally published documents and documents of local interest.^[21,22]

The National Document Delivery System (*Országos Dokumentum-ellátási Rendszer*) ensures enhanced access for users to library holdings not held in their local public library or at libraries open to the general public. Established in 1998 and operated by the Hungarian National Library, it provides a searchable database for locating library materials for interlibrary loan. The Hungarian government supports this program by not only financing the central database, but also by funding the acquisition of materials and their postal or electronic delivery to the patrons located anywhere, including small villages. This program is one of the central elements of the government's strategic initiative that considers public libraries and libraries open to all users as pivotal institutions of the information society. The program helps library services in rural areas reach the same level of access as any larger library. Services include physical and electronic document delivery, online information services, organization of exhibitions, and events.

School Libraries

Teaching library skills has been part of the National Curriculum since 1995. The 2003 Law of Public Education stipulates the existence of libraries and the hiring of librarian-teachers in most public schools. However, the quality of these school libraries, their holdings, and their equipment is not always up to the required level; their conditions depend mostly on the economic circumstances and leadership of the given educational institutions. The number of school libraries in Hungary exceeds 4000. The National Pedagogical Library and Museum (NPLM) develops their standards and coordinates their professional

work. The NPLM provides a wide array of resources for librarian-teachers. Libraries of private educational institutions have to satisfy the same standards and requirements as public schools.^[23,24]

Special Libraries

In spite of the early appearance of the first book collections in hospitals (like Rókus Hospital at the end of eighteenth century, and a number of libraries from the early twentieth century on) most medical libraries were founded after the 1956 Library Law. The medical library network counted more than 300 specialized libraries during the early 1960s and more than 400 during the mid-1970s. This abundance was followed by a period of mergers and shutdowns during the 1980s and 1990s that paralleled a controversial integration and reform process for medical institutions. The Hungarian Medical Library Association counted 171 medical libraries in 2000, excluding the libraries of medical schools.^[25,26]

The Library of the Parliament (*Országgyűlési Könyvtár*) and the libraries of the law schools are the special legal libraries in Hungary. Though law firms have book collections, law libraries have not been institutionalized. The first searchable online law collections appeared during the late 2000s.

Religiously affiliated libraries are maintained by the Catholic, Calvinist, Lutheran, Eastern Orthodox, and Unitarian churches, and Jewish religious communities, and offer access to their collections for users within and outside of their religious institutions and communities. *Theca*, the shared bibliographic database of religiously affiliated libraries, provides access to a growing proportion of their post-1850 holdings.

Digital Library Collections and Services

The Hungarian Electronic Library (*Magyar Elektronikus Könyvtár*^[27]) collects and preserves freely available documents on Hungary and Central Europe in the areas of culture, education, and scholarly research. The depository is open to the public not only for access, but also for uploading materials. A description helps prospective contributors with content and format criteria. Added works must be out of copyright or accompanied by the permission of the copyright holder. Contributed documents are uploaded via file transfer protocol to the depository. People are invited to send their own works and suggest documents stored on other servers for transfer. This archive of books—and, in small proportion, maps and music scores—was a private initiative of enthusiastic librarians in 1994. It became a project of the National Information Infrastructure Development Program as well as a later popular movement. In 2007, the number of works archived in the depository exceeded 5000. Part of the archives is the result of a major digitization project:

the Digital Library of Hungarian Studies (*Hungarológiai Alapkönyvtár*), making almost 4000 classical texts and reference materials available in the area of Hungarian studies. Both the latter project and the Hungarian Electronic Library are coordinated by the National Széchényi Library.

The National Electronic Periodicals Archive and Database (*Elektronikus Periodika Archivum és Adatbázis*^[28]) is a catalog and archive of Hungarian and Hungary-related periodicals. The archives also include digitized or born-digital resources which are either stored here or are linked from other sites. Users can search by title, year, subject, and full text (if the resource is locally archived). In conjunction with the periodical titles, the depository presents the text of the copyright agreement with the publishers of the resources about the use of the full text. Opened in 2004, the EPA is rapidly growing; its aim is to become a comprehensive gateway to Hungarian and Hungary-related periodical literature. In 2007, it included about 1200 periodical titles of which 153 were locally archived and more than 1500 were linked from another site.

The John von Neumann Digital Library (*Neumann János Digitális Könyvtár*^[29]), named after the Hungarian-born American mathematician, is a state-funded institution performing digitization projects of Hungarian cultural heritage. Its collections are selected from among the most valuable and respected literary works and secondary literature. The Neumann Library supports e-learning from early childhood to continuing education. The deposited works are freely available for reading and full-text searching. Parts of the Neumann Library include: the *Bibliotheca Hungarica Internetiana*, a virtual collection of critical and popular editions of the works of Hungarian—literary and nonfiction—classical authors; the Digital Literary Academy (*Digitális Irodalmi Akadémia*), a gateway to the works of the best living Hungarian literary authors; a collection of children's readings, audio and visual materials, animated stories, videos and games, and the Reading is Fun program (*Olvasni jó*); The latter part includes carefully selected educational materials for the youngest generation.

The Hungarian National Library is digitizing the available pieces of King Matthias' fifteenth-century library. In 2007, the *Bibliotheca Corviniana Digitalis*^[30] included 36 codices—all held in the National Library—and provided information about the other "Corvinae" held in libraries in 16 countries. Full codicological description, an analysis of their art historical context, and a full bibliography completes the collection.

The National Digital Data Archive (*Nemzeti Digitális Adattár*^[31]) is a searchable catalog of metadata representing Hungarian and Hungary-related content: virtual libraries, museums, archives, and other digital documents (including the items held in the above-mentioned databases). The cooperation, including more than 50 partner institutions, is based on the use of a standard metadata

system and shared data operation. The NDA provides a catalog of metadata, a search engine, and their technological background; it does not run digitization projects itself.

A large number of other archives, catalogs, and databases are available at their own Web sites or through the National Digital Data Archive: e.g., Fine Arts in Hungary (*Képzőművészet Magyarországon*^[32]), Budapest Photo Archive (*Budapest Képtár*^[33]), Hungarian Film History Online (*Magyar Filmtörténet online*^[34]), the Data Archive of the Social Research Center TÁRKI (*Társadalomtudományi Digitális Adattár*^[35]), and the BMC Hungarian Music Information Center (*BMC Magyar Zenei Információs Központ*^[36]), among many others.

LIBINFO^[37] is a Hungarian national online reference service. A few dozen listed librarians provide answers to e-mailed reference questions within 48 hr. The service operates on a consortial basis; questions are triaged to the most appropriate librarian expert on the list. The service is hosted and coordinated by the Hungarian National Library.

Library and Information Science as Discipline and Profession

Scholar bibliographers were the first representatives of library science in Hungary in the eighteenth and nineteenth centuries (*Péter Bod*, 1712–1769 *Károly Szabó*, 1824–1890, *Géza Petrik*, 1845–1925), and bibliographies and collections of authors' biographies were the first works of the discipline. *József Szinnyi* (1830–1913), founder-director of the Periodicals Collections of the National Library wrote the most comprehensive 14-volume Hungarian bio-bibliography on pre-1900 authors published between 1890 and 1913.^[38] He also published the first comprehensive repertory of Hungarian and foreign serials in three volumes.^[39] Library science became an academic discipline in 1901 at the University of Kolozsvár (now Cluj) and in Budapest in 1914. *Pál Gulyás* continued Szinnyi's work, publishing a main bio-bibliographical work on post-1900 authors. Early twentieth-century librarians wrote the first works on specific issues (cataloging etc.) of librarianship, and the first research center dealing with the discipline (*Országos Könyvforgalmi és Bibliográfiai Központ*, National Center for the Book Trade and Bibliography) was established in 1923; it was transformed into a National Center for Libraries in 1945. The successor of this center is the *Institute of Librarianship* (*Könyvtártudományi Intézet*), operating within the framework and in the building of the National Library (*Országos Széchényi Könyvtár*).

Several prizes honor libraries and librarians: the *Library of the Year Award*, the *Széchenyi Ferenc*, and the *Szinnyi József prize* are the most important ones.

Journals of librarianship include the *Könyvtári Figyelő* (Library Review) and the *Könyv, Könyvtár, Könyvtáros* (Book, Library, Librarian)—the latter more interested in

international issues and technology, the former aimed for a broader audience more focused on current issues in Hungarian librarianship. These journals are published by the National Library and the Library Institute, respectively. The journal *Tudományos és Műszaki Tájékoztatás* (Scientific and Technical Information) deals with information science and promotes the latest developments in information technology. *Hungarian Library and Information Science Abstracts* reviews Hungarian publications of the discipline for an international audience.

Education for LIS

Prior to World War II, experts with degrees in some of the humanities disciplines were recruited to librarianship. University-level librarian programs started in 1948. Currently, two levels of librarian programs are offered at colleges and universities: BA and MA, some of them with an information studies specialization. Four of the universities (Budapest, Pécs, Szeged, and Debrecen) have Ph.D. programs.

Institutions such as the National Library offer mid-level education for future library assistants. A high school diploma is the prerequisite for these programs.

Professional librarians are required to participate in 120 hr of organized continuing education every 7 years; certificates are provided by institutions accredited specifically to offer these courses.

Professional Associations

Founded in 1935, the Association of Hungarian Librarians (*Magyar Könyvtárosok Egyesülete*) is a civil nonprofit organization with more than 2000 individual and 60 institutional members. Its ten professional sections reflect the main interests and specializations of Hungarian librarians. The Association abides by the Code of Ethics of Hungarian Librarians that sets behavioral standards for professionals.

The Alliance of Libraries and Information Institutes (*Informatikai és Könyvtári Szövetség*) is a national organization of about 230 member institutions. Its mission is to enhance library services and cooperation as well as increase the profile of member libraries. A series of further associations bring together special types of libraries (*Magyar Orvosi Könyvtárak Szövetsége*, Association of Medical Libraries; *Publika Magyar Könyvtári Kör*, Public Library Group; *Egyházi Könyvtárak Egyesülése*, Association of Ecclesiastic Libraries, etc.)

ARCHIVES AND ARCHIVAL SCIENCE

(The main sources of this section are works by Blazovich and Müller^[8] and Dóka.^[40])

Overview of Legislation

The 1995 LXVI Law regulates the charge and operation of Hungarian archives. The conditions for research in archival resources are specified partly by this law and partly by the 1992 LXIII Law dealing with the protection of private personnel data and the availability of public data. These laws apply equally to repositories holding documents of archival value whether they are financed and/or operated by the state, municipalities, organizations, churches, trade unions, or private citizens.

National Archives and Services

The holdings of the Hungarian National Archives (*Magyar Országos Levéltár*) include an immense historical collection of governmental and private documents. They also provide access to the complete archives of the ruling party of the 1945–1989 period, large historical collections of maps, coins, photos, stamps, and microfilm. The National Archives include materials formerly held in the New Hungarian Central Archives (*Új Magyar Központi Levéltár*), an institution that operated and collected current governmental documents between 1970 and 1992. The National Archives manages the e-Archives (*e-Archívum*), an online union catalog of nationwide archival holdings. Since e-Archives is a relatively new tool, retrospective conversion is still going on. A number of the finding aids are digitized, and full-text digitization of a few important holdings has also begun. The database of digitized materials (*Digitarchív*) is searchable.

A special state archive, the Historical Archives of the Hungarian State Security (*Állambiztonsági Szolgálatok Történeti Levéltára*), was established in 2003 holding documents produced between December 21, 1944 and February, 1990. Its collections include documents of state security organizations, state security documents of the Ministry of Defense and the Hungarian People's Army—all operating during the period of state socialism.

A few additional archives are operated and funded by the state: the Archives of Military History (*Hadtörténeti Levéltár*) holding historical and current governmental documents of the military and its predecessors, the Archives of Environmental and Water Issues (*Környezetvédelmi és Vízügyi Levéltár*), and the Archives of the Central Statistical Office (*Központi Statisztikai Hivatal Levéltára*).

Hungary's 19 counties, the capital city, Budapest, as well as some towns have their own archives collecting local official and private documents.

College and University Archives

Documents on Hungarian higher education held in different collections go back to the seventeenth century. However, the first university archive was not established until 1958 at the Loránd Eötvös University, Budapest. In the

second half of the 1970s and early 1980s, six universities deposited their documents into specialized archives, soon followed by the rest of the universities.^[41] From 1992 on, college and university archives united into an association to assist member institutions to organize their documents more quickly and to publish the most important sources.

Film Archives and Other Audiovisual Archives

The Hungarian National Film Archives (*Magyar Nemzeti Filmarchívum*) collects, processes, preserves, and stores films and other documents related to Hungarian motion picture production and reception. The Film Archives serves as a depository for films created in Hungary.

The National Audiovisual Archive (*Nemzeti Audiovizuális Archívum*) is a depository of the locally produced programs of the most important Hungarian television channels and radio stations. The cataloging records of the programs are freely accessible for searching through the Internet. An amended Hungarian copyright law made access to the full content of the records and recordings possible for education and research purposes via a network of public terminals (“NAVA points”) located in libraries open to the public, in schools, in museums, and in print, visual and audio archives.

Other Kinds of Archives: Corporate and Religious Archives, Manuscript Repositories, Historical Societies

The Archives of the Hungarian Academy of Sciences (*MTA Levéltára*) holds the historical and current documents of the central governing bodies and offices of the organization. Since the Academy plays a pivotal role in granting postgraduate degrees in all disciplines, the archives hold these documents as well.

Private archives open to the public include the archives of the trade unions (*Szakszervezetek Archívuma*), the Institute of Political History (*Politikatörténeti Intézet*), some parties (e.g., *Független Kisgazda és Polgári Párt*), and a variety of religious archives.

The Catholic Primate Archives of Esztergom (*Esztergomi Prímási Levéltár*) is the largest ecclesiastic archive. Its importance follows from the size of its territory as well as the importance of the Bishop residing here. Highlights of the huge collection include 1200 pre-1526 charters and all minutes from the Canonica Visitation (1557–1940). Other religiously affiliated archives include a number of Protestant, Serbian Orthodox, Jewish, and Unitarian institutions.

The Open Society Archives, a product of the philanthropic activity of the Soros Foundations network, obtains, preserves, and makes available research resources for the study of Communism and the Cold War, particularly in Central and Eastern Europe. The archives of the research institute of Radio Free Europe constitute the core of the

OSA’s collections. They also hold the complete documentation of the *Index of Censorship*, a journal published in London.

Archival Science as a Discipline and Profession

Traditionally, the profession of archivist has been closely connected to the profession of historian in Hungary. Degrees in economics, German, Latin, library science, and others may also be an educational basis for archivists. Only somewhat more than half of the professionals working in Hungarian archives have a degree in Archival Science. Scholar archivists mainly publish works on historical sources rather than the methodological, theoretical, and technological issues of the profession.

The Educational and Methodological Center in the National Archives (*Oktatási és Módszertani Központ*) offers courses on all levels and provides certificates for archivists and archivist assistants. The College of Archives (*Levéltári Kollégium*), an expert body appointed by the Ministry, participates in the governing, quality control, and strategic planning of the field. Current strategic plans (e.g., *A levéltárak középtávú informatikai stratégiája és feladatterve, 2006–2010*,^[42] Medium Term Information Technology Strategy and Goals in Archives, 2006–2010) target the need for archivists who are skilled in information technology, the need for archives better equipped with current technology, and the need to archive electronic documents.

Two main journals are published in the field: the *Levéltári Közlemények* (*Archival Digest*, published since 1923) is the publication of the National Archives, and deals with the analysis and publication of primary historical sources, as well as main issues of archival science nationally and internationally. The *Levéltári Szemle* (*Archival Review*, published since 1951) is the publication of the Association of Hungarian Archivists; it targets the practical work of archivists, facilitates cooperation, and publicizes main Hungarian events of the profession. The *ArchivNet* (subtitled “Historical Sources”) is a new online periodical edited by the National Archives since 2001. Its main goal is full-text electronic publishing of twentieth-century historical sources.

Prizes that recognize archivists’ outstanding achievements include: the *Ervin Szabó Medal* and the *Gyula Pauler prize*.

Education for Archivists and Records Managers: Examinations, Certification, University-Level Programs, and Continuing Education

Higher education for archivists is provided by some universities (currently the Eötvös Loránd in Budapest, the Debrecen, Miskolc, and Szombathely) offering BA and MA programs in history. History majors may specialize in Archivist Studies and get a BA or MA degree. History

and other MAs and PhDs may take specialized postgraduate courses offered by the National Archives and other major archives in order to earn a certificate. Accredited archival institutions (e.g., the National Archives) offer courses and certificates for future archivist assistants. The prerequisite for these courses is a high school diploma. This system of education is in flux and modifications are expected. Accreditation of educational institutions is provided by the Committee of Archivist Accreditation (*Levéltári Akkreditációs Szakbizottság*) appointed by the Ministry for Education and Culture.

Professional Associations

Several associations unite archivists in Hungary. The largest is the Association of Hungarian Archivists (*Magyar Levéltárosok Egyesülete*), which, until 1986, was a section of the Association of Librarians. Three other associations bring together archivists specializing in particular areas: The Council of Municipal Archives (*Önkormányzati Levéltárak Tanácsa*), The Alliance of Religious Archives (*Magyarországi Egyházi Levéltárosok Egyesülete*), and the Coalition of Hungarian University and College Archivists (*Magyar Felsőoktatási Levéltári Szövetség*) focus on professional issues relating to a specific type of archives and to archivists working in these institutions.

Electronic Records as Archival Documents

The issue of electronic documents and their preservation has been a key concern in the twenty-first century. Standards, equipment, skilled archivists, and funding for the handling, storing, and processing of the electronic documents have been lacking. Archivists are aware of the need, and their strategic plan^[42] contains action items related to the institutional, technological, and personnel aspects of archiving electronic documents. The realization of this strategic plan is expected in the near future.

Preservation of Documents in All Forms and Formats

The Ministry for Education and Culture exercises quality control over state-financed and municipal archives, as well as private archives open to the public, via a body of experts—the College of Archives (*Levéltári Kollégium*)—that conducts annual surveys and analyses of the individual archives. These analyses include a review of preservation activities among other issues. Lack of space is a major problem as well as lack of funding for improved air-conditioning and climate control. The annual reviews oversee preservation efforts that produce surrogate copies: archives make microform and, increasingly, digitized copies of endangered paper-based materials. Recently, the College raised the issue of the preservation of nonpaper-based documents (photos, sound and video recordings, films, CDs,

DVDs, and electronic documents) and suggested solutions. Preservation standards for these nontraditional materials are under consideration.

MUSEUMS

(Most of the information on individual museums is based on data published in *Magyarország múzeumai. Múzeumlátogatók kézikönyve*.^[43])

Overview of Laws

The 1997 CXL Law pertains to museums as well as to libraries. The law lays down the rules for the protection of cultural heritage monuments and objects as well as the ways in which they may be declared protected (e.g., change of ownership has to be traced under specific circumstances; the Ministry has to give permission if they are taken abroad, etc.). It specifies conditions for archeological digs and the protection of these sites. With regard to museums, it defines the prerequisites and methods for the founding and closure of museum institutions. Additionally, it defines the specifications for types of museums in relation to the ways they operate and get funding.

Seven hundred and seventy-two museums and galleries operate all over the country. The Ministry for Education and Culture oversees the activity of museums partly directly and partly via a number of expert bodies: the National Museum Council (*Országos Múzeumi Tanács*), the Accreditation Committees for Museology and Protection of Objects of Museological Value (*Műtárgyvédelmi és Muzeológiai Akkreditációs Bizottságok*), and the Museum College (*Múzeumi Kollégium*), a body that evaluates grant applications.

Museums of National Jurisdiction

The National Museum (*Nemzeti Múzeum*) is located in its nineteenth-century neoclassical building and holds more than 1 million archaeological, numismatic, historical, and artistic artifacts.^[44] Highlights of the collections include the coronation cloak of the Hungarian kings and the sword of Saint Stephan (*Szent István*), the first king of the country. The most valuable crown jewels (the crown, the orb, and the scepter) are permanently exhibited under the main dome of the Parliament building and can be seen during guided tours. The following sections present the vast collections of the National Museum and are divided into sections encompassing archeological and historical materials, photographs, coins, and historical paintings. Staff dedicated to data processing, information technology, preservation, restoration, and library services ensure the professional operation of the museum.

The Ethnographic Museum (*Néprajzi Múzeum*) is one of Europe's largest ethnographic collections with 140,000

Hungarian artifacts and more than 50,000 international artifacts. Its permanent exhibit presents traditional Hungarian culture.

The most complete historical collection of Hungarian fine arts (more than 100,000 pieces) is held and part of it permanently exhibited at the Hungarian National Gallery (*Magyar Nemzeti Galéria*), located in one of the most spectacular buildings of the Buda castle. The Gallery provides a variety of services such as research service on Hungarian works of fine arts; this service is available to the public. The Gallery also supplies permissions for transporting Hungarian works of art abroad. Housed in a neoclassical building located with the *Műcsarnok* (a gallery of contemporary art) on the large and impressive Heroes' Square, the Museum of Fine Arts (*Szépművészeti Múzeum*) holds an internationally renowned collection of fine arts, which includes an exceptional series of Spanish paintings by El Greco, Velázquez, Murillo, and Goya. For a fee, the museum's museologists and art historians will provide expert opinions about the authorship, quality, authenticity, etc. of the art pieces submitted for appraisal by patrons.

Documents and objects related to Hungarian literature are collected and exhibited in the Petőfi Museum of Literature (*Petőfi Irodalmi Múzeum*). The Manuscript Archive of the Museum is the largest collection of its kind in Hungary. The Audiovisual Collections hold recordings of interviews and conversations with the most eminent representatives of Hungarian literature. The Reception Databank monitors, collects and processes the German, French, English, and Italian reception and criticism of Hungarian literature, and makes these results accessible for the public.

The stunning majolica-roofed and eclectic Secession-style building of the Museum of Applied Art (*Iparművészeti Múzeum*) is Ödön Lechner's work; the museum was the third of its kind in the world in 1857 after the opening of similar museums of design in London and Vienna. Its four major collection areas are ceramics, glass, and china; textiles; furniture; and gold and silversmithing.

Additional government-sponsored museums are the Museum of Medical History (*Orvostörténeti Múzeum*), the National Technical Museum (*Országos Műszaki Múzeum*), the Agricultural Museum (*Mezőgazdasági Múzeum*), the Museum of Transportation (*Közlekedési Múzeum*), the Museum of Military History (*Hadtörténeti Múzeum*), and the Budapest Historical Museum (*Budapesti Történeti Múzeum*)—all located in the capital, Budapest; and the Outdoor Ethnographic Museum (*Szabadtéri Néprajzi Múzeum*) located in Szentendre, a small township north of Budapest.

Since the early 1970s, a number of national parks have been opened. The Hortobágy National Park (*Hortobágyi Nemzeti Park*) was the first, presenting the natural history and current wildlife of the Hungarian plain, followed by national parks representing different regions, landscapes,

fauna, and flora, such as the *Kiskunság*, *Bükk*, *Aggtelek*, and *Őrség*.

Major Art Museums and Galleries

In Budapest, in addition to the Museum of Fine Arts and National Gallery, a series of museums maintain permanent exhibits of art (e.g., the Ludwig Museum, *Ludwig Múzeum*, in the royal castle area, the Picture Gallery of the Capital Museum of Kiscell, *Fővárosi Képtár Kiscelli Múzeum*, etc.). A number of smaller museums present the works of individual artists, (e.g., *Victor Vasarely*, a Hungarian-born French painter; *Imre Varga*, a twentieth-century sculptor, etc.). Galleries such as the *Műcsarnok* (Palace of the Arts), *Vigadó Galéria* (Vigadó Gallery), and the *Ernst Múzeum* (Ernst Museum) offer exhibition spaces for contemporary art. The *Sculpture Garden* (Szoborpark) is an unusual collection of public sculptures which have been removed from their original location and gathered together in one place. These sculptures, produced 1945–1989, express the spirit of state socialism.

A few other cities have a high concentration of museums and galleries. Szentendre has been a favorite town of artists, and subsequently is home to the many memorial museums which have been created to display their artistic achievements. For example, there are museums for the works of *Margit Anna*, *Imre Ámos*, *Jenő Barcsay*, *Béla Czóbel*, *János Kmetty*, and *Lajos Vajda* (twentieth-century painters) the *Ferenczy family* (nineteenth- and twentieth-century painters and sculptors), *Margit Kovács* (twentieth-century ceramic artist). The latter, located in a late eighteenth-century building, and presenting ceramic sculptures of unique character, consistently attracts record numbers of visitors.^[45]

On the museum walk of the southern Hungarian city of Pécs, the Janus Pannonius Muzeum (*Janus Pannonius Múzeum*) is an umbrella organization for a number of local museums which include, among others, the collections of the Modern Hungarian Picture Gallery (*Modern Magyar Képtár*); the Exhibit of Zsolnai Ceramics (*Zsolnai Kerámia Kiállítás*); a museum for the works of *Victor Vasarely* and another for the works of *Amerigo Tot*, both born in Hungary; the most complete collection of works by early twentieth-century expressionist Hungarian painter, *Tivadar Csontváry Kosztka*; and a large collection of works by *Erzsébet Schaár* (a twentieth-century sculptor).

Kecskemét, a township southeast of the capital, became a center of folk art. The Museum of Hungarian Folk Design (*Magyar Népi Iparművészeti Múzeum*) holds a rich collection of folk arts and crafts. *Szórakoténusz*—the name is part of a counting rhyme—is a museum of folk childrens' games and toys. The Museum of Hungarian Naïve Art (*Magyar Naív Művészek Múzeuma*) also presents paintings and sculptures originating of folk art.

Science and Natural History Museums

The Science Museum (*Természettudományi Múzeum*) split from the National Museum in 1934. Its animals, plants, humans, minerals, and geology sections hold millions of species and other scientific objects. About the history of the main Hungarian museums see work by Holló.^[46] The National Technical Museum (*Országos Műszaki Múzeum*) holds historical artifacts of Hungarian science, technology, and industry.

An interesting series of museums hold historical artifacts related to industry and transport. The Museum of Transportation (*Közlekedési Múzeum*) opened in 1899 in Budapest, preserving the objects exhibited at the large 1896 show that commemorated the 1000th anniversary of the conquest of Hungary. The museum collects boats, trains, cars, and other transportation vehicles. The exhibition in the Expo of Flying and Space (*Repüléstörténeti és Űrhajózási Kiállítás*) completes this collection—all of the above are located in Budapest. The Kner Printing Museum (*Kner Nyomdaipari Múzeum*) in Gyomaendrőd displays books and other imprints as well as the workshop of a famous nineteenth-century bookmaker. The Tokaj Museum (*Tokaji Múzeum*) in Tokaj collects tools, objects, and documents related to winemaking. Two museums in the west Hungarian town of Sopron (*Bányászati Múzeum*, *Bányászati Emlékmúzeum*) and museums in Oroszlány and Tatabánya—all mining areas—present objects and historical documents related to mining. In the city of Herend, in the original late classicist style building of the Herend china factory, the Museum of the Art of China (*Porcelánművészeti Múzeum*) presents the history of this world famous company established in 1839.

Religiously Affiliated Museums

The Christian Museum in Esztergom (*Keresztény Múzeum*) is the richest among the private collections in Hungary.^[47] Highlights of the holdings include a late medieval collection (Passion paintings of Master MS, the Calvary altar of Tamás Kolozsvári, etc.) and a collection of postmedieval paintings, design, and graphics. The museum is located in a seventeenth-century Jesuit monastery.

Established in 1909, the Jewish Museum (*Zsidó Múzeum*) collects and preserves cultural, historical, and religious objects of Hungarian Jewry.^[48] In spite of a successful 1938 exhibit presenting the long history of Hungarian–Jewish life beginning with King Béla IV's charter (1256) and a large exhibit of Jewish artists in 1939, the museum had to close due to the anti-Semitic laws and government. Thanks to two museologists of the National Museum, the most important pieces of the collections were hidden in the cellars of the National Museum, survived the war, and were given back to the institution afterward. The museum is now located in a building right next to the main synagogue of the capital,

on the place of the house where Tivadar Herzl, founder of the Zionist movement, was born. More than 800,000 items are held in the collections, the largest such collection in Central Europe.

Szentendre, the small artist city north of Budapest, is the home of the Serbian Orthodox Museum (*Szerb Ortodox Múzeum*) located in a building of the Orthodox Church. Icons, goldsmith works, and other objects reflect the culture of seventeenth- and eighteenth-century Serbs in Hungary.

Historical, Anthropological, and Archaeological Museums

A number of larger cities have their own general historical museums. The Ferenc Móra Museum (*Móra Ferenc Múzeum*) in Szeged owns 273,000 objects, and offers permanent exhibitions, among them an exhibition of Avar finds and another on pharmacies. The István Dobó Castle Museum (*Dobó István Vármúzeum*) in Eger presents spectacularly the castle's Turkish siege of 1552 through the objects that have remained from the sixteenth century. The collections of the King Stephan Museum (*Szent István Király Múzeum*) in the city of Székesfehérvár present the ruins of the medieval cathedral, along with archaeological finds and a large collection of paintings.

A number of historical sites became museums. *Aquincum's* Roman ruins present the remains—mosaic floor, organ, water pipes, etc.—of a prospering city on the border of the Roman Empire (currently in north Budapest). *Visegrád*, the ruins of King Matthias' castle have been transformed into a museum. The National Historical Park (*Nemzeti Történeti Emlékpark*) in Ópusztaszer is the site where, according to the legend, Hungarian tribes, went into a blood union with Árpád's leadership after the conquest of the Carpathian basin in 896. A painting of exceptional size (about 18,000 sq.ft) depicts the historical event. One site in Budapest and another one in Sopron, west Hungary, keep alive the memory of Hungarian Jewish communities: the Medieval Jewish Prayer House (*Középkori Zsidó Imaház*) exhibits the remains of Jewish tombstones and gothic carved stones of the synagogue. The Medieval Old Synagogue (*Középkori Ó-Zsinagóga*) in Sopron goes back to the early gothic era around 1300.

Many historic homes have been preserved and turned into museums all over the country; each municipality pays special attention to those houses and sites that recall memories of a great artist, writer, or politician. Homes of great statesmen (e.g., *Széchenyi István* in Nagycenk, *Lajos Kosuth* in Monok), aristocrats (the *Duke Esterházy* family in Fertőd), poets, and writers (e.g., *Ferenc Kazinczy* in Sátoraljaújhely, *János Arany* in Nagykőrös), artists (e.g., *József Rippl-Rónai* in Kaposvár, *Lajos Kassák* in Budapest), and musicians (e.g., *Ludwig van Beethoven* in Martonvásár, *Franz Liszt*, *Béla Bartók*, *Zoltán Kodály* in

Budapest) are preserved, maintained, and presented to the general public.

Zoos and Botanical Gardens

The Budapest Zoo, officially called *Fővárosi Állat- és Növénykert* (Animal and Plant Garden of the Capital), opened in 1866 with 500 diverse animals. János Xántus, an ethnographer-traveler, was its first director. The zoo became a research institution during the 1950s. The institution is widely known for its nature conservation activities.

The Botanical Garden of Vácátót (*Vácrátóti Botanikus Kert*) is the largest of its kind in Hungary with the largest collection of living plants. Its creation dates back to the first half of the nineteenth century. The garden became the site of the Botanical Research Institute of the Hungarian Academy later on. Twelve other botanical gardens present the fauna of the other Hungarian regions; the most important of them is the Arboretum of Szarvas (*Szarvasi Arboretum*), the site of the University of Horticulture and Food.

Digital Museum Exhibits and Services

Every museum and gallery has a Web site offering basic information about services and collections as well as digital samples of the holdings.

Access to the most important digital museums and exhibits is provided by the National Digital Data Archive (*Nemzeti Digitális Adattár*^[31]). The digital collection Fine Arts in Hungary (*Képzőművészet Magyarországon*^[32]) provides a comprehensive history of the fine arts (painting and sculpture) in Hungary from the eleventh century to the twentieth century. It does not include contemporary fine arts. In 2007, the collection held 5200 digital reproductions. The permanent digital exhibition of the National Gallery (*Nemzeti Galéria*^[31]) presents 1000 digital reproductions of its most important holdings; viewers may choose to visit the exhibit with the help of a virtual guide. A smaller collection of the holdings of the Christian Museum of Esztergom (*Keresztény Múzeum*^[49]), 164 digital reproductions, is also available through the NDA. Archaeological sites, historical buildings, and objects protected by the state are cataloged (11,000 records) by the Office of Cultural Heritage (*Kulturális Örökségvédelmi Hivatal*^[50]). Digital photos and descriptions of 3200 historical buildings (fortresses, castles, churches, etc.) are also available through the NDA database among a number of further collections.

Museology as a Discipline and Profession^[51]

Museum professionals are experts in art history, archaeology, ethnography, and history, as well as the sciences and engineering, specializing in museological aspects of their respective fields. Leading figures of the field have conducted research and contributed to the emergence of a

museology discourse from the early nineteenth century on. Thanks to their scholarly activity, the legal and institutional framework of this field has developed steadily since the 1880s. The first organization dealing with the inventory and protection of historical monuments (*Műemlékek Országos Bizottsága*) was created in 1881. This institutional background helped professionals produce a series of comprehensive works on Hungary's historical monuments^[52–54] that served as a basis for the creation of a thorough register, topography, and standardized approach to sites and buildings of historical importance. Though collecting of ethnographic, historical, scientific, and other types of artifacts as well as art started in the eighteenth century among the aristocracy, and extended to the affluent middle class in the third part of the nineteenth century, no laws and institutions protected collections held by collectors and museums until 1949. The decree on museums (1949) at last made it compulsory to keep standardized records and statistics of museum holdings as well as private property of museum value. These legal and institutional changes have provided a data-oriented background and overview to the type of museological research that deals with the collection, preservation, exhibition, etc. of museum holdings nationwide. The outstanding scholarly production of nineteenth and early twentieth century paved the way for museologists on individual collections, objects, and institutions, and for approaches that map and evaluate the whole cultural heritage. Efforts have been made (especially by the publications of László Mravik^[55]) to identify and reclaim art works illegally moved out of the country before and during the Second World War.

Magyar múzeumi arcképcsarnok, a recently published biographical lexicon lists all those experts who worked and published during the last two centuries. About 2000 expert professionals have been working in Hungary's 772 museums in 2005;^[56] their research contributions are published in books and scholarly periodicals.

Several periodicals focus on museums. *Múzeumi Közlemények* (Museum Proceedings) concentrates on theoretical and methodological issues of museology. The content of *Múzeumi Hírlevél*'s (Museum Newsletter) is more practical; its articles describe current issues and events pertinent to Hungarian museums. *Magyar Múzeumok* (Hungarian Museums), published by the Pulszky Society, is an illustrated magazine targeting a broader audience; it publishes special issues dealing with specific types of museums and subjects related to them.

The best museologists, curators, and managers are annually recognized by the *Ferenc Pulszky* and *Károly Pulszky Prizes*, museums by the *Museum of the Year Award*.

The main academic frameworks for museum research are departments of history and ethnography of the major universities (in Budapest, Debrecen, Miskolc). Expert museum curators and managers conduct research at their institutions; publications are requirements for promotion.

In 2004, the International Council of Museums (ICOM) accepted the Code of Ethics of Museums that has been subsequently accepted by the Hungarian National Committee of ICOM. The document has been translated and published in Hungarian. This code sets standards for professional activity and performance.

Education for Curatorship and Museum Administration

Archeologists, historian-museologists, art historians, and other experts may become museologists. The history and ethnography departments of a few universities offer BA and MA degrees in “museologist specialization” within their disciplines. Postgraduate courses and certificates are offered for future curators at the Hungarian University of Fine Arts (*Magyar Képzőművészeti Egyetem*) and the Management Section of the Pulszky Society (*Pulszky Társaság*). Courses for cultural managers are also offered by the Pulszky Society as well as within the framework of continuing education at some universities (e.g., *Janus Pannonius University*, Pécs).

Professional Associations for Curators and Museum Administrators

The Pulszky Society, Hungarian Association of Museology (*Pulszky Társaság, Magyar Múzeumi Egyesület*) is the largest Hungarian association of museum professionals; its sections deal with such concerns as preservation, management, art history, and continuing education. The association promotes museums and museology, facilitates cooperation among institutions and professionals, publishes a journal, and votes annually on two awards—one for a museum, and one for a professional. Other associations unite special interest museums and museologists including the Association of Public Collections (*Közügyűjtemények Szövetsége*) and the Association of County Museums (*Megyei Múzeumok Igazgatóságainak Szövetsége*).

Key Contemporary Issues

Current priorities are listed in the *Alpha Program*,^[57] the mid-range plan for Hungarian museums—most of these priorities relate to the strategic plan of the cultural government of Hungary as a new member country of the European Union. Broadening access to the collections, and strengthening their educational role is the top priority. The second major priority is to develop requirements for open and visitor-friendly museums in each museum service. This goal has consequences for infrastructure as well as for the level and quality of cooperation between schools and museums. The government supports this goal by not only providing free access to museums for schoolchildren, but also providing free public transportation (including

long distance train) to groups of schoolchildren to 14 major museums of national jurisdiction. Annual special events like the Museum May Day (*Múzeumi Majális*) and Museum Night (*Múzeumok Éjszakája*) attract more and more people to these institutions, and transform museums into popular meeting places. The third major priority is qualitative development and preventive preservation of the collections, as well as digital access to collections information. This complex professional goal also harmonizes with the EU strategy of preservation declared by the International Centre for the Study of the Preservation and Restoration of Cultural Property (ICCROM) in Vantaa, Finland, in 2000.

CONCLUSION

Current tendencies and future plans of Hungarian libraries, archives, and museums harmonize with trends that characterize these areas worldwide and interests (and financial resources) that the European Union has elaborated for its member countries. The Strategy of Libraries for 2008–2013 (*A könyvtárügy stratégiája 2008–2013*) is currently (in 2007) being widely discussed.^[12] Its main goals are the continuation of the development of libraries and library access in rural areas; delivery of around-the-clock access to library materials from any location; and improved ability for the disabled to access libraries. The digitization of extant primary and secondary Hungarian literature as well as current publications will also continue.

The mid-range strategic plan of Hungarian archives identifies the major deficiencies in the current situation as follows: lack of financial resources, lack of appropriate technological knowledge and skills among archivists; lack of theoretical–methodological background. In order to resolve these problems, the mid-range plan (*A levéltárak középtávú informatikai stratégiája és feladatterve, 2006–2010*)^[42] projects the transformation of archives from institutions providing merely storage and preservation for the materials, and access to the materials for researchers into institutions that provide access to their materials 24/7 from any location. The document defines future archives as basic institutions of a democratic society, and proposes that the government finance a breakthrough project of e-government and e-public-administration. The plan envisages the creation of an e-archive within the framework of the Hungarian National Archives, and the establishment of a degree in information and archive management as well as records management—both related to public administration rather than to traditional history.

The most important efforts in the museum field will continue to be related to the Alpha Modernization Program which has as goals making museums more accessible and user-friendly, further developing their relationships to education, and increasing the mobility of collections and professionals nationwide and internationally.

Every major trend of Hungarian libraries, archives, and museums over the next 7 years (2007–2013) will certainly be harmonized with or based on the “culture program” of the European Union, accepted for the aforementioned period of time by the European Parliament.^[58] The general objective of this program is to “enhance the cultural area common to Europeans with a view to encouraging the emergence of European citizenship.” Its central objectives are “supporting the transnational mobility of professionals in the cultural sector; encouraging the circulation of works of art and artistic and cultural products beyond national borders; and promoting intercultural dialog.”

ACKNOWLEDGMENTS

I wish to thank Dr. Antal Stark, Assistant State Secretary; Dr. Annamária Víg, Head of the Department of Public Collections; Prof. György Sebestyén, Director, Institute of Library and Information Science; Dr. Péter Fodor, Director, Ervin Szabó Könyvtár; as well as the expert librarians of the Könyvtári Intézet and Országos Levéltár for giving me opportunities for consultation, supplying materials not readily available in the United States and answering my numerous queries regarding many issues of this entry. I am grateful to Dr. Annamária Víg and Dr. Antal Stark, Hungarian Ministry for Education and Culture for the statistical data.

APPENDIX: KEY DATES

896	Hungarian tribes settle in the Carpathian Basin.
997–1038	Stephen of the Árpád dynasty rules the country.
1000	Stephen is converted to Christianity. Christianization of the population follows.
1001	Foundation of the first monastery and monastic library (Pannonhalma).
1055	The earliest written record extant in the Hungarian language: the foundation charter of the Tihany abbey.
1192	The earliest Hungarian text, a funeral sermon, inserted in the Latin Pray Codex.
1241	Mongolian Tatars invade and devastate the country.
1367	Foundation of the first university (Pécs).
1458–1490	King Matthias, a true Renaissance ruler, elevates the country to a high European standard.
1460	Foundation of the Bibliotheca Corviniana, King Matthias' library.
1473	Publication of the first printed book (in Latin), <i>Chronicle of Buda</i> .

1526	Turks defeat the Hungarian army at Mohács, and the King dies in the battle.
1533	The first book in Hungarian language is published in Krakow.
1541	Turks occupy Buda. Hungary is split into three parts.
1613	Official documents of the Habsburg Monarchy start to be deposited in archives.
1686	Buda is recaptured from the Turks.
1703–1711	Ferenc Rákóczi II, Prince of Transylvania, leads an unsuccessful uprising against the Habsburgs.
1749	Foundation of the Habsburg monarchic archives in Vienna, the <i>Haus-, Hof-, und Staatsarchiv</i> .
1756	Foundation of the Hungarian Royal Archives, predecessor of the Hungarian National Archives.
1780	Publication of the first Hungarian journal, <i>Magyar Hírmondó</i> .

First half of the nineteenth century

	A national reform movement is launched for the political and economic modernization of the country and the development of its Hungarian national identity.
1802	Foundation of the Hungarian National Museum and Library by count Ferenc Széchenyi.
1825	István Széchenyi founds the Hungarian Academy of Sciences.
1844	Hungarian becomes Hungary's official language.
1848–1849	Revolution and war for independence.
1866	Opening of the Budapest Zoo. Foundation of the Library of the Parliament.
1870–1900	A series of new museums are opened: Ethnographic, Fine Arts, Applied Arts, etc.)
1867	Compromise with the Habsburgs; beginning of a double-centered monarchy of Austria-Hungary. Foundation of the Hungarian Statistical Office and its Library.
1907	Publication of the first periodical on libraries and museums, <i>Múzeumi és Könyvtári Értesítő</i> .
1904	Opening of the first public library, <i>Fővárosi Könyvtár</i> .
1914–1918	World War I; the Austro-Hungarian monarchy is Germany's ally. After the defeat, the Monarchy disintegrates.
1920	The Trianon Treaty reduces Hungary's territory.
1923	Publication of the first periodical on archives, <i>Levéltári Közlemények</i> .

- 1935** Foundation of the Association of Hungarian Librarians, includes archivists until 1986.
- 1944** Hungary is occupied by Nazi Germany.
- 1945** The Soviet Army liberates Hungary.
Central institutions are founded to administer libraries, archives, and museums.
- 1946–** Nationalization of most private libraries, archives, museums.
- 1947** Beginning of Communist control; establishment of Stalinist dictatorship.
- 1948** University level program for librarian education is established.
- 1956** Uprising against Stalinism.
Foundation of the Gorky Library, a center for Russian culture.
The first Library Law is accepted.
- 1965** Cautious economic market reforms, the New Economic Mechanism, are launched.
- 1985** The Hungarian National Library moves to a building of the Royal Castle.
- 1986** Foundation of the Association of Hungarian Archivists.
- 1988** Beginning of transition from state socialism to capitalism and democracy.
- 1990** Multiparty parliamentary democracy is established. The Soviet army leaves Hungary.
- 1995** LXVI Law regulates Hungarian archives.
- 1997** CXL Law regulates Hungarian libraries and museums.
- 1999** Hungary becomes a full member of NATO.
- 2002** The first online union catalog, *MOKKA*, goes live.
- 2004** Hungary joins the European Union.

Hypertext and Hypercard: Early Development [*ELIS Classic*]

Susan K. Kinnell

Consultant, Santa Barbara, California, U.S.A.

Carl Franklin

Consultant, Columbus, Ohio, U.S.A.

Abstract

The ease of linking and hopping from one text to another that we associate today with the World Wide Web was implemented in a different context prior to the Web. The creation of “hypertext” has a long and interesting history prior to the Web, as this entry demonstrates. At the time it was issued, the HyperCard software application was expected to be the foundation of a widely-used new means of information organization. We can see now that the key ideas of hypertext were present in HyperCard, without the ease of use of subsequent World Wide Web features.

—*ELIS Classic*, from 1992

INTRODUCTION AND DEFINITION

Hypertext has been defined by many people in different ways. It has been called nonsequential writing,^[1–3] the creation and representation of links between discrete pieces of data,^[4] an associative information management system,^[5,6] and a database with “active” cross references.^[7] However defined, the point is this: electronic links are created between pieces of information in a machine-readable document and a computer is used to make the quick leaps between those pieces of linked information. A computer is required to define those links in the course of creating a hypertext document, and a computer is required to execute those links during the course of reading or using that document. It can be described, written, and talked about, but the essence of hypertext comes from using the speed of a computer to make those links.

Imagine the scope and contents of an extensive reference work. Generally, it will have title and cataloging information; a contents page; various entries that each contain headings, subheadings, footnotes, see and see also references, and notes; there might also be charts, maps, illustrations, or photographs; and in the back, a bibliography, index, glossary, and one or more appendices. When using such a volume, the researcher scans the title first, then probably the contents and index pages, looking for the desired material. Once an appropriate entry is found, its contents are scanned, key word definitions are checked, the notes and references are scanned, and then the bibliography is reviewed. All of this requires considerable page turning and page flipping, as the researcher verifies that the book contains essential information, before he or she even starts to read it and take notes from it. Consider the options available to any researcher if all of this material was linked electronically and could be called up at the

stroke of one key. To access a glossary with specific definitions, double check the source of a quote, to consider further study along somewhat different lines, verify the extent of a particular source, or even jot down the salient facts and figures culled from that source—all of these things can now be done electronically (even taking notes on the sources being utilized) without great amounts of effort and time being expended.

As mentioned earlier, reference books often contain illustrations such as maps, charts, or photographs. Given the speed and memory capabilities of modern computers, this has become one of the most appealing features available when creating a hypertext document. Modern computers can access plain photographs such as exist now in reference books, and they can also provide moving video pictures from a variety of sources and audio capability by accessing tape recorders, CD-ROM players, or prerecorded sounds on a floppy disk. The hypertext reference work can provide, for example, a life of Beethoven, a picture of him, a related discussion of his country and fellow composers, and a sample of sounds from his compositions. It might even include access to some video footage from a film or documentary of his life.

As the user moves through such a collection of reference material (called hypermedia if more than one medium is being used), he or she has the ability to select and choose the most pertinent material. The user can move through the material and select paths or links to other pieces of information that are the most relevant. Presumably no two people use a reference work with exactly the same motives or needs, and their paths through the material are now no longer restricted to structured, linear information. Each may select the same material, but in a different order, or each may spend varying amounts of time in different areas. This flexibility and user-defined

approach is probably the most significant area of hypertext research currently being undertaken at major universities.

The relationship between the way people think, and the way they learn is of considerable consequence to researchers in education and psychology, as well as in the newer fields of computer and cognitive science. Hypertext presents a new way of looking at material, free from the constraints of linear access. People do not think in a linear fashion and their minds are structured into associative patterns. Access to material or information that allows and even encourages associative browsing is highly desirable, and test results just beginning to be reported in academia are highly supportive of this theory. "Learning by discovery" is becoming a popular basis for hypotheses in educational research.

Finally, in understanding the concept of hypertext, it is necessary to learn a few new words in context. There are four elements to a hypertext program that must be understood, and although software packages may name them differently, their meaning does not change. These four words are: node, button, link, and jump. Node refers to a discrete collection of information. This may range from a single word to a picture, a video clip, or supplementary text. A button represents the beginning point of a connection from one node to another. The link is that connection between nodes and a jump represents taking the link to a new node. In its simplest fashion, therefore, a hypertext document may have two nodes: for example, a paragraph describing a picture and the picture itself. Within the paragraph is a button that links the paragraph to the picture. When the button is pressed, the user jumps to the picture via a link that was pre-established during the creation of the hypertext document.

Another way of looking at this kind of system is to imagine a telephone network. In the simple system described above, there are two nodes (two telephones), one button to press (the dial), and a jump (or call) to make across one link (telephone line). In a more complex telephone system, many calls can be made from one telephone, but it is entirely dependent on how many lines have been strung across the land by telephone workers first.

Electronic technology allows us to access a number of places or things (telephones, video broadcasts, nodes, etc.) from a single unit on our desk or in our home. Keeping this electronic network idea in mind will help in understanding the concepts of a hypertext document and the links it contains.

HISTORY

Popular knowledge of the technology known as hypertext began with the introduction of HyperCard by Apple Computer, Inc. at MacWorld Expo in August 1987. But before that time, a surprising number of people were working on

hypertext projects, or had contributed substantially to the growing field of knowledge in this area. Chief among these people are H.G. Wells,^[8] Vannevar Bush,^[9,10] Ted Nelson,^[1-3] Doug Engelbart,^[11] and Alan Kay.^[12]

H. G. Wells

In 1936, H.G. Wells delivered a lecture at the Royal Institution of Great Britain, entitled "World Encyclopaedia." In it, Wells posited the theory that man would be faced with too much information to be able to deal with it logically, and that he would not be able to find the material he needed. To rectify this situation, Wells came up with the idea of a world encyclopedia which would be continuously updated and easily accessible to anyone anywhere. He did not trouble himself with the technical details of how this would be achieved, only that it would definitely be necessary.

Vannevar Bush

The article by Vannevar Bush entitled "As We May Think," was published in the August 1945 issue of *Atlantic Monthly* magazine. In it, Bush, science advisor to President Roosevelt, describes a machine he calls the memex (p. 77),

a device in which an individual stores all of his books, records, and communications, and which is mechanized so that it may be consulted with exceeding speed and flexibility. It is an enlarged supplement to his memory. . . . It affords an immediate step, however, to associative indexing, the basic idea of which is a provision whereby any item can be caused at will to select immediately and automatically another. This is the essential feature of the memex. The process of tying two things together is the important thing.

Even today, there is no better way to describe or define hypertext. When you consider that Bush described an earlier version of his memex in 1939 (more than 50 years ago!), you realize that Bush is indeed one of the most visionary of the hypertext pioneers.

When his entry was published in *Atlantic Monthly* (and another version in *Life* shortly thereafter), Bush found that his ideas created a great deal of controversy and inspired a number of other researchers. He continued to write about his ideas and belief that mechanization was one way to sort through the ever-increasing piles of information that confront researchers. This process of sorting and selection by means of association was central to the memex and recurs throughout all of Bush's writing.

In 1967, Bush wrote "Memex Revisited" in which he discussed his earlier entry and the technical developments that had taken place since 1945. He concluded that the transistor, video tape, high-speed circuitry, and the ability

to compress information storage had all contributed to the theoretical practicality of his memex. Bush reiterated his belief that the mechanization of “selection by association” would bring about a successful personal machine that would allow a human being to “think creatively and wisely, unencumbered by unworthy tasks . . .” and that he will be able to “face an increasingly complex existence with hope” (p. 100). In words very reminiscent of Wells, Bush said: “Each generation will receive from its predecessor, not a conglomerate mass of discrete facts and theories, but an interconnected web which covers all that the race has thus far attained” (p. 99).

An interesting sidelight to the work going on during this period was a project at MIT known as Intrex (Information Transfer Experiments). Described in Stephen Salmon’s book, *Library Automation Systems*,^[13] Intrex began in 1965 and was terminated in 1973. Its principal aim was to provide an “augmented catalog” (p. 121) for libraries that would provide more information online beyond the usual bibliographic references and subject headings. It also attempted to provide the storage and retrieval of full-text documents to library patrons using terminals. When the project was introduced in 1965 to a large conference of librarians, engineers, publishers, government officials, and others, one of those present was Vannevar Bush. He praised the efforts of the Intrex group as reaching far beyond his original ideas of “analytical machinery” (p. 5).

Theodor Holm Nelson

Ted Nelson^[1-3] is considered by many to be the father of hypertext. Certainly he was the one who gave it the name, as well as the term hypermedia. He would be the first to laugh at the “overnight” success of hypertext since he began working on his theories and articulating them back in the 1960s. His first published work on the subject was “The Hypertext” in the *Proceedings of the World Documentation Federation* in 1965. A more well-known work, *Computer Lib/Dream Machines*, was published in 1974 and then reissued in 1987 by Microsoft Press. This marvelous collage of ideas, facts, fantasies, drawings, trivia, and profound thinking is must reading for anyone interested in computers or hypertext.

One of Nelson’s biggest projects is called Xanadu (after Samuel Taylor Coleridge’s “magic place” in the poem *Kubla Khan*), which he started as a graduate student in 1960. Nelson wanted the Xanadu project to store all of the world’s literary resources in an electronic format and to link parts of those documents and pieces of text to create new composite documents. In 1988 the Xanadu project was taken over by Autodesk, creators of large information management systems.

Nelson also has a special interest in education and was one of the first to recognize the value of hypertext in both teaching and learning. In an entry entitled, “No more teachers dirty looks. . .”, he said:

Let the student pick what he wishes to study next, decide when he wishes to be tested, and give him a variety of interesting materials, events, and opportunities. . . . Under such circumstances, students will actually be interested, motivated to achieve far more than they have ever achieved within the normal instructional framework.

Nelson continues his work today, lecturing at conferences and workshops, and further developing the concepts of the Xanadu project.

Douglas Engelbart

Douglas Engelbart^[11] began his work at the Stanford Research Institute in the 1960s and was heavily influenced by Vannevar Bush’s theories. He worked on a system called NLS (ON Line System) that was designed to link text segments of 3000 words or less. In addition, there was a filter capability that selected information from the database of segments, and a visual capability that allowed the user to view the results of his linked (filtered) selection. NLS subsequently evolved into a hypertext system called Augment, used internally and marketed by McDonnell Douglas. Augment is used primarily for text editing, and features windows and electronic conferencing for multiple users. Engelbart used the term “augment” to describe his system because it augments or extends the human intellect, and his major goal is to aid “knowledge workers.” Engelbart is also the developer of the mouse, windows, and numerous other technological advances, and works today at Stanford University on Operation Bootstrap.

Alan Kay

Alan Kay^[12] was present at a demonstration done by Engelbart in 1968 on the system he had developed, and it had a profound effect on him. Kay had been formulating his ideas on education and computers during the time he had spent learning to program computers in the Air Force and doing his doctoral work at the University of Utah. There he became involved with the domain of artificial intelligence research as well as the work of Seymour Papert^[14] at MIT, who designed the programming language for children called LOGO.

Kay was convinced that the ultimate goal of all software was the enhancement of the ability to learn. He subsequently wrote a language called Smalltalk and began work on the ultimate, small personal computer—something he called the “Dynabook.”

Kay was working in those days at Xerox PARC, and he was very concerned with the effect of different kinds of media on children. He wrote an entry in 1977 in which he described the Dynabook as a “dynamic medium for creative thought” and from there he went on to explore the idea’s enormous potential for education as well as creative processes in computer simulation. Defining simulation as the power to see what you can imagine. Kay has gone on

to develop what he calls the “fantasy amplifier,” to preserve and extend that sense of wonder that children have. Kay also pioneered the use of symbols (icons) instead of words for telling a computer what to do next.

After PARC, Alan Kay went to work for Atari as chief scientist. He now works for Apple Computer as an Apple Fellow and indulges his lifelong interests in education and music.

ACADEMIC AND CORPORATE PROJECTS

At the academic and corporate level, a number of prominent scientists and researchers have been working on research projects over the past several years. These hard-working and dedicated people are contributing vital elements to the growing body of knowledge on hypertext and hypermedia.

The Jefferson notebook

Mark Chignell and Tyde Richards are two members of the Jefferson Notebook team at the University of Southern California in Los Angeles. Formerly called Project Jefferson, the project was conceived and designed as a tool for writing research papers in the Freshman Writing Program at USC. Organized as an electronic notebook with access to the instructors assignments, background information, citations of relevant documents, and commercial databases loaded on the mainframe computer at the USC library. Project Jefferson has become the basis for a number of similar applications in varying disciplines such as psychology, anthropology, and library science.

Project Emperor-I

Professor Ching-chih Chen^[15] is the Associate Dean of the Graduate School of Library Science at Simmons College in Boston. Dr. Chen has authored many entries and books on the subject of information technology and management for libraries and scholars. She is also editor of the journal *Microcomputers for Information Management* and is the principal director of Project Emperor-I, a project supported by a number of government and business organizations as well as Simmons. The project combines videodisc and microcomputer technology, providing over 100,000 graphic images of the first emperor of China and his terracotta army of warriors and horses excavated in 1973 in Xian, China. Using a HyperCard interface, the project provides not only these images, but film footage, audio tracks of interviews, and related study materials and it also provides the audio and textual materials (including screen design) in Chinese as well as English. It is a major humanities project that has been utilized by Apple's new Visual Almanac, and the videodiscs will soon be available to schools in this country.

Notecards

Randall Trigg, Frank Halasz, and Tom Moran have contributed substantially to the NoteCards project at the Intelligent Systems Lab at Xerox PARC in Palo Alto, California. Trigg is the author of the first doctoral dissertation on the subject of hypertext. NoteCards is a network-based system designed for processing ideas, and has formed the basis for a number of important discoveries on the storage, linking, and retrieval of information, and the concept of the card as a structure for pieces of information has been widely used by HyperCard as well.

Intermedia

The Institute for Research in Information and Scholarship (IRIS) at Brown University in Providence, Rhode Island, has been doing hypertext research for over 20 years. Andries van Dam, Paul Kahn, and Nicole Yankelovich, along with Karen Smith, Norman Meyrowitz and many others have made substantial contributions to our knowledge of hypertext in education. The current project at Brown is Intermedia, a complex and interactive system for creating hypermedia courseware that allows the student to make links to related materials in other areas.

Hyperties

Another university that has devoted time and energy to hypertext research is the University of Maryland. Here Ben Schneiderman, long interested in the human-computer interface, helped develop Hyperties (ties = The Interactive Encyclopedia System) project. Other hypertext research has been done at the University of Maryland by Gary Marchionini, Ronald Weissman, and others.

Bioquest

At the University of Oregon in Portland under the direction of Nils Peterson, a major effort has been made to create a computer-based introductory biology course. Complete with elaborate laboratory simulations. BioQUEST intends to enhance the students' ability to recognize and solve problems. BioQUEST includes text materials, applications software, and an online reference source in HyperCard.

Project Perseus

Elli Mylonas, Kenneth Morrell, and Gregory Crane are three researchers on Project Perseus at Harvard University in Boston. This project is a collection of materials on the classical Greek world, and includes 100 megabytes of text and several thousand images.

Superbook

The Bell Communications Research (Bellcore) lab in Morristown, New Jersey, has done some superlative work in hypertext and hypermedia, including SuperBook. Developed by Tom Landauer among others, SuperBook is a system that reads in an existing (and usually very large) document already in electronic format, and then allows the reader—via the dynamic table of contents, search capabilities, and windows—to access specific parts of the document. It has proven particularly effective in the use of very large technical documents.

HYPERMEDIA AND HYPERTEXT SOFTWARE

Implementations of hypermedia and hypertext for personal computers vary greatly in price, ease of use, and capability. In general, some packages have special facilities for working with electronic text or graphics while others excel at integrating computers with other devices such as videodisc or CD-ROM players. Some are useful for developing applications while others are standalone products. Ideally, the choice of software should be based on a combination of price, ease of use, number of features, and use, but a previous hardware commitment can significantly affect this decision. Therefore, the next entry will provide an overview of hypermedia and hypertext on three personal computer/software systems: the Apple II, MS-DOS, and Macintosh computers.

Apple II Software

HyperScreen

Published in early 1990 by Scholastic Software and developed by George Brackett, HyperScreen works with all members of the Apple II family. HyperScreen supports graphics, sound, animation, and video.

HyperStudio

Unlike HyperScreen and Tutor-Tech, Roger Wagner's HyperStudio will run only on the Apple IIGS. Like HyperCard, each screen is a card and a collection of cards is a stack. HyperStudio is unique among the packages discussed here because it comes with software and hardware to allow the digitization and playback of audio from a variety of sources. In addition, it works with Apple's Video Overlay Card, allowing a developer to integrate video with other forms of hypermedia.

Tutor-Tech

Techware began selling its Tutor-Tech software in 1985. Like many other hypermedia programs, the basic building

block is the page. A page is one screen of information and may contain buttons for linking to other pages or to control external devices such as videodisc players and speech synthesizers. Although Tutor-Tech is neither as powerful nor as flexible as HyperCard, it offers the basics of hypermedia to a wide audience.

MS-DOS Software

Guide

Introduced in mid-1987 for computers running Microsoft Windows, Guide 2.0 for the PC performs almost identically to its counterpart on the Macintosh. This can be an important selling point for schools that have both Macintosh and MS-DOS equipment. As noted above, Guide works particularly well with large amounts of text although it also can incorporate graphics. Version 2.0 does not come with a programming language. Guide 3.0 for Windows, just announced, adds a programming language and support for dynamic data exchange with other programs.

HyperPAD

Billed as a HyperCard clone for the PC, HyperPAD runs on machines with a minimum of 384K of RAM and MS-DOS 2.0. The program has basic hypertext features and an excellent built-in programming language called PADtalk. In Hyper-PAD, a file is a pad and a screen of information, a page. Pages can use only character-based graphics since the program runs on monochrome monitors. A good touch is the ability to use either the keyboard or a mouse to control all the functions of the program. Like HyperCard, the package comes with several built-in programs: a calculator, a telephone dialer, a puzzle, and so on. In short, Jim Lawyer and his team at Brightbill-Roberts have done a reasonable job of transferring the non-graphics-related functionality of HyperCard to MS-DOS computers.

Hyperties

Hyperties was originally developed by Dr. Ben Shneiderman and others at the University of Maryland in the early 1980s. Cognetics Corporation now distributes the program. Hyperties provides basic hypertext capabilities to machines with as little as 256K of RAM. Applications can be developed as text-only or a combination of text and graphics. Each application is built around one or more entries and a collection of entries is called a database. In line with its straightforward approach, users can choose between running the program using the keyboard or a mouse.

KnowledgePro

Created by Bev and Bill Thompson. KnowledgePro for DOS combines hypertext and expert systems technology and requires 512K RAM to run. In KnowledgePro, a file is called a knowledge base and consists of a number of topics. Users can add sophisticated features to topics using the built-in programming language. Although KnowledgePro for DOS uses character graphics, bit-mapped images can be added via the Graphics Toolkit. For those interested in more advanced forms of hypermedia, the Videodisc Toolkit enables KnowledgePro to control the Sony LDP 2000 videodisc player.

LinkWay

Developed in response to Apple's HyperCard, LinkWay is IBM's flagship hypermedia product. Created by Larry Kheriaty, it requires a minimum of 384K, a CGA display, a Microsoft-compatible mouse, and one floppy drive. A LinkWay file is called a folder and a screen of information, a page. A page may contain data, buttons, and graphics. LinkWay comes with a paint program, a text editor, a font editor, and sample applications. Although not as powerful as HyperCard, LinkWay does bring some excellent hypermedia tools to the PC.

Macintosh Software

More hypertext/hypermedia software is available for Apple Computer's Macintosh line than any other type of computer. Sporting a mouse and windowing interface, the Macintosh is a natural for hypertext and hypermedia. Development environments include ArchiText, Business Filevision, Guide, Intermedia, Plus, and SuperCard. Inasmuch as HyperCard is the most well-known hypertext software, it will be treated in a separate entry following that describing other Macintosh software.

Business Filevision

An early form of Business Filevision was introduced in August 1984, making it the first hypermedia software for the Macintosh. The product, created by Howard Metcalfe, combines hypermedia with a flat-file database. The result is a synergistic product with more power than HyperCard for certain applications such as geographic information systems. Like ArchiText, Business Filevision lacks a programming language and this makes it less versatile than other products.

Guide

Guide 2.0 draws on several years of research on reading electronic documents conducted by Dr. Peter Brown at the

University of Kent in Canterbury, England. In 1985, Guide was ported to the Macintosh and then, 2 years later, to the IBM PC. Basically, Guide acts like a word processor with extra features for linking text and graphics. Its trademark is its ease of use.

Intermedia

Developed by Norman Meyrowitz and others at Brown University, Intermedia runs under the A/UX operating system (Apple's version of UNIX). A copy may be obtained through the Apple Programmers and Developers' Association. Intermedia comes with elegant drawing, mapping, and writing tools. Although few schools have the necessary computer resources to run Intermedia, its sophistication points the way for the future of hypermedia software on the Macintosh.

Plus

Plus is available in the United States from Spinnaker Software under a special agreement with its West German developers. While Plus can run most HyperCard stacks, it is much more than a clone. Its programming language, PPL, is a superset of HyperTalk. Overall, it is an excellent development environment for those who find the limitations of HyperCard too restricting. More importantly, Spinnaker expects to release versions of Plus for Microsoft Windows and OS/2 in 1990, which should make it possible to run HyperCard stacks on IBM and compatible computers.

SuperCard

Like Plus, SuperCard from Silicon Beach Software is not a clone of HyperCard, but an extension. Its extra capabilities come at a price, however. For example, running the program in color requires 2 MB of RAM. HyperCard stacks may be imported into this environment, but they run more slowly than applications developed using SuperCard. SuperCard also uses some unexpected terminology: a group of cards is called a window and a group of windows, a project. The program's strengths are its animation/drawing tools and its SuperTalk programming language.

HYPERCARD

Bill Atkinson and the beginning of HyperCard

Bill Atkinson, developer of HyperCard, graduated from the University of California at San Diego with a Bachelor's degree in chemistry, and went on to get a Master's in electrical engineering at the University of Washington in Seattle. After graduation, he worked for

Rah Systems, and was president of Synaptic Systems Corporation, a company he founded in Seattle.

Atkinson went to work for Apple Computer, Inc. in 1978, adapting a Pascal program to the Apple II. He wrote the first graphics program for the Macintosh. MacPaint, but he is most well known for the development of HyperCard. He calls HyperCard a “software erector set” for building other kinds of applications and programs. His insistence that this new program be given away by Apple with every new Macintosh computer is certainly one of the major reasons for the success not only of this particular program but of the whole concept of hypertext itself. He believes strongly in the concept of sharing knowledge, both in the immediate sense (he visualized hundreds and thousands of people sharing “stacks” of information through HyperCard), and in the overall sense, in which information and results are linked and shared so that duplication of effort is avoided.

Atkinson is currently an Apple Fellow and is investigating the factors that go into the makeup of a good teacher, with the hope of incorporating those factors into future software developments.

Hypercard basics

HyperCard uses an index card metaphor. That is, a screen of information is a card and a collection of cards is a stack. (See Figs. 1 and 2.) The mouse is used to select choices from pull-down menus as well as to navigate among cards in a stack. One innovation to the basic card file concept is the use of backgrounds. The same background may be shared by all of the cards in a stack or each card can have its own distinctive look.

Ready-to-run stacks included in the standard HyperCard package are a rolodex card file, a calendar, an appointment book, and a notebook with activities. There are also demonstration stacks with pictures, quotations,

Fig. 1 HyperCard.

Fig. 2 The Home Card in HyperCard.

and ideas for buttons, cards, and stacks. Going through any of these sample stacks of working through the Intro Stack is a good way to get to know HyperCard.

HOW HYPERCARD WORKS

There are nine major elements in the HyperCard browsing environment: buttons, fields, cards, backgrounds, stacks, the Home Stack. Recent, the Help Stack, and the Message Box. The first five are the basic elements of a HyperCard application: the next three are navigational aids (ways to help move around and through stacks); and the Message Box is a communications device between the user and the HyperCard.

Building a Stack

Every HyperCard application (or stack) consists of a number of cards. A card is equivalent to a screen of information and may contain fields, buttons, and backgrounds. Fields contain text and buttons signal the existence of a link between two cards or fields. Fields and buttons can be layered on top of each other in the card foreground. The background of each card in a stack may be the same or each card may have a different look.

Navigational AIDS

The Home Stack is the index to the entire program. The first card in the Home Stack is the Home Card and is displayed when HyperCard is launched. There are icons on the Home Card that connect to the applications or stacks currently available.

Clicking on Recent shows up to 42 of the most recently viewed cards in the program. This function helps the user keeps track of his or her location in the program by

highlighting the current card. It also permits direct access to any of the 42 cards.

The Help icon (a question mark on the Home Card) or the keyboard equivalent Command-? takes the user to the first Card in the Help Stack. This stack contains basic information about HyperCard.

The Message box

The Message box is brought up by holding down the command key and pressing the letter m. The box appears as a small text field at the bottom of the screen. The Message box may be used to send any one-line command directly to HyperCard. For example, the user may tell HyperCard to “Find” something, “Go” somewhere, or “Play” a noise like “beep” or “boing.” Other commands include “The Date,” “The Time,” and “Show” (which displays a particular card or series of cards). (See Figs. 3 and 4.)

USING HYPERCARD

HyperCard has five levels of accessibility that accommodate the novice as well as the experienced user. In order of increasing complexity these are browsing, typing, painting, authoring, and scripting. Each level builds on the capabilities of the previous level.

Browsing: The Browsing level provides access to short file and edit menus, permits movement from card to card, and allows the use of the Browse tool.

Typing: The typing level allows the user to explore HyperCard’s stacks search for text, and edit text.

Painting: By moving to this level, the user gains full File and Edit menus. Paint tools (but not Button and Field tools), and the Power Keys option.

Authoring: At this point, the user has access to the Object menu and the Button and Field tools.

Fig. 3 HyperCard Help.

Fig. 4 HyperTalk Script.

Scripting: Finally, the scripting level places all the capabilities of HyperCard at the user’s fingertips. Features available only at this level include script editing and access to the Message box even when it is hidden.

GETTING STARTED

The first time HyperCard is launched, the Home Card will appear. Pointing and clicking with the mouse on one of the icons takes the user to the linked stack. One of the easiest ways to get started is to change existing stacks by altering the text or the pictures on the various cards. More adventuresome users may decide to create a new stack via the pull-down menu.

Text Editing

HyperCard has basic facilities for entering and editing text. All of the standard editing tools are present for adding, changing, and deleting text as well as for moving blocks of text and formatting margins, font styles, etc.

Graphics

HyperCard comes with a complete set of painting tools very similar to those in MacPaint. These tools help create bit-mapped graphics by turning pixels (picture elements) on or off. An extension of this capability is the “Fat Bits” option that enlarges the painting to allow editing of individual pixels. HyperCard does not have drawing tools—tools which create graphics as objects.

When a particular painting tool is selected, three additional menus (paint, options, patterns) appear in the menubar. These new menus provide additional tools to enhance or modify a painting. These menus can also be “torn off” and placed in convenient spots on the screen so

Fig. 5 Text and HyperCard.

they are visible while working on a painting but do not interfere with the image.

HyperCard's graphics tools are moderately sophisticated and powerful. They are also easy to use and follow the patterns of other similar graphics programs. Combined with the Cut-Copy-Paste tools that are also available in the text-editing mode, the graphics tools are more than adequate for most tasks. (See Figs. 5 and 6.)

Scripting with Hypertalk

The most sophisticated and powerful part of HyperCard is its built-in programming language called HyperTalk. Just as text or graphics may be edited, it is also possible to alter the way things work by using the authoring tools. The first step is to switch to the Scripting level. This level is adjusted by going to the Home Card and clicking on the arrow for the previous card (the User Preferences Card). This card allows the user to select any one of the five levels desired.

Fig. 6 A customized Home Card.

One advantage of HyperTalk is that it looks and sounds like ordinary English. Jargon is not needed in order to write simple scripts. Other advantages are that it closely resembles object-oriented programming, which has a simplicity of approach and design. Message passing between objects is the basis of object-oriented programming, and also of HyperTalk. All activity in HyperCard involves messages, whether from the system itself, between stacks, or among cards. HyperCard's major strength is its programmability. Virtually any application can be created using HyperTalk. This is the main reason for the proliferation of stacks all over the country—and even throughout the world. Teachers, librarians, students, and business people alike can use HyperCard to create a unique application.

Advanced features

The power of HyperCard does not end with scripting. The programmers at Apple Computer have made it possible to actually add features to HyperTalk through XCMDs and XFCNs. XCMDs are external commands (written in another programming language such as Pascal). XFCNs are external functions that are similar to XCMDs except that when they finish executing, they return a value. In effect, XCMDs and XFCNs make HyperTalk one of the most flexible programming environments in existence.

Hypermedia Interface

A number of options are available to produce sophisticated educational stacks involving hypermedia. For example, Apple Computer sells the CD-ROM and Videodisc. Toolkits to enable HyperCard to communicate with optical disc systems. Additionally, hypermedia developers can add synthesized speech to their projects through the public-domain HyperMacinTalk stack. For those interested in sound effects or digitized speech, there's the MacRecorder from Farallon. Animation buffs, on the other hand, will want to look into Video Works II from MacroMind and HyperAnimator from Bright Star. VideoWorks II allows the creation of digital movies that can be accessed from HyperCard. Hyper Animator adds talking actors with realistic expressions to stacks. In short, almost any conceivable enhancement can be made to HyperCard for a price.

SUMMARY

HyperCard is only one of the software packages available that enables the user to experiment with the world of hypertext and hypermedia. It is the most widespread, however, and probably the cheapest and easiest to obtain. As more sophisticated applications are developed that use video, laserdisc, sound, and graphics, more and more people will find a way to integrate them into their work and

personal information management. The changes that have taken place within the computing world in the last two decades alone are astounding, and the promise is for many more. Voice-operated computers, virtual realities, and fully integrated applications will become the norm. The idea of *linking* that is so central to hypertext is a powerful feature of all of the current and promised technologies. The associations that we have in our minds for the management of the information we need and use are the associations we will actually be able to employ through our computers, thanks to hypertext and hypermedia technology. The world of tomorrow is on our doorstep.

Illumination [ELIS Classic]

Abdul Moid

University of Karachi, Karachi, Pakistan

Abstract

“Illumination is the art of embellishing manuscripts with gold or silver and bright colors,” according to the author. “The art of illumination or manuscript painting is ancient and widespread. It flourished in Japan, China, India, Central Asia, the Near East, and Europe, as well as in pre-Columbian America. Basically, however, illumination is a medieval art *par excellence* that flourished mostly in Europe and the Orient until the introduction of engraved illustrations in printed books.” The history of ancient and medieval illumination is traced, with emphasis on Europe, the near East, and Central Asia.

—*ELIS Classic*, from 1974

INTRODUCTION

Illumination is the art of embellishing manuscripts with gold or silver and bright colors. In contemporary usage illumination incorporates illustration, historiation, miniatures, paintings, and designs not only in polychrome but also in monochrome. Illumination is derived from the French *enluminure* and Latin *illuminare* meaning “to light.” The art of illumination, though ancient, is generally restricted to medieval manuscripts on parchment characterized by the use of gold or, rarely, silver to light the ornamented letters, chapterheads, marginal borders, painted scenes, and sometimes the whole page.

COLOR ILLUSTRATION

Illustration in color is an ancient technique basically employed to clarify the contents of a manuscript. The ancient Egyptians used the technique on papyrus rolls. Historiation or the illustration of texts by relevant paintings or continuous scenes in historical sequence is also an ancient practice.

Miniature, derived from *miniare* in Latin, means to paint in red or with *minium*, a brilliant red pigment. The word “miniature” is commonly used for painted individual illustrations in ancient manuscripts and medieval codices. It is also applied to portraits, landscapes, and figural scenes of minuscule dimension in a manuscript. Paintings in Islamic manuscripts are usually referred to as miniatures. Miniatures may be executed without the use of gold or silver, while in illumination the use of gold is a must.

The main colors used in the embellishment of manuscripts were red, blue, and gold, and less frequently purple, yellow green, plain black, and white. These colors were made from earth minerals or plants, for example red from minium, and later from cinnabar, purple from

turnsole or shellfish (*Murex*), yellow from turmeric roots, white from burnt bones, black from sloe berries, green from copper, etc.

The art of illumination or manuscript painting is ancient and widespread. It flourished in Japan, China, India, Central Asia, the Near East, and Europe, as well as in pre-Columbian America. Basically, however, illumination is a medieval art *par excellence* that flourished mostly in Europe and the Orient until the introduction of engraved illustrations in printed books.

ANCIENT AND CLASSICAL ILLUMINATION

Ancient Egypt

Illumination owes much for its origin to the techniques of illustration used on papyrus rolls by ancient Egyptians. These illustrations were pictorial rather than ornamental, an artistic development due to the fact that one of the earliest forms of Egyptian writing was pictographic. The illustrations in continuous scenes are used to explain the text.

Several of these earliest texts of the second millennium B.C. are now preserved in the British Museum, and are commonly called the *Book of the Dead* as they used to be kept along with a dead body in the tomb.

The earliest known copies containing the *Helipolitan Recension* are assigned to the eighteenth dynasty (1570-ca. 1350 B.C.). The texts are written in black ink, but the titles and the first words of the chapters are written in red ink, and the designs or vignettes are in black outline.

Another text, known as *Papyrus of Ani*, has a border of two colored lines, the inner one brick red and the other dull yellow. The vertical columns of text are broken at intervals by pictures and vignettes in brilliant color, illustrating the passage of Ani and his wife to the other world. Numerous gods are also represented.

Hunefer Papyrus shows the use of systematic pictorial designs in continuous scenes in monochrome and water colors of great delicacy and brilliance. The illustration depicts scenes of a funeral procession with the mourners, wailing women, and a reader who recites the funeral services, and another Anubis holds the outer coffin before the family of Hunefer.

Another copy of the *Book of the Dead* shows Orisis, outlined in black, wearing a garment decorated with bright red dots and a crown and neck ornament of inlaid gold. Border and outlines are drawn in black ink. This color scheme marks the beginning of illumination, which was continued in Christian and Islamic examples.

Greco-Roman Period

Greek art, which mainly flourished in Hellenistic Alexandria, shows a strong ancient Egyptian influence of papyrus style. A fragment of a papyrus roll (Bibliothèque Nationale, Paris) assigned to the second century, has three columns of writing, each bearing illustration in Egyptian style. The figures, however, are drawn in black and have heavy brush strokes. The garments are pink and blue-gray and the faces are brown.

The surviving materials of the classical Greek period are very few and most of them were found in Egypt, apparently dating from about the fourth century B.C. to the seventh century A.D. In the early fourth century, vellum and parchment superseded papyrus and became the chief material for ornamental writing.

The *Ambrosian Iliad* (Biblioteca Ambrosiana, Milan) is the earliest extant fragmentary example of an ancient Greek manuscript on vellum in roll form. Only 58 illustrations on the verso of the 52 leaves of the vellum have survived, probably out of 386 leaves with 240 pictures. The colors used are red, blue, purple, and green with outlines in ink, and a bright yellow in place of gold. Landscape appears in the backgrounds. Frames of red and blue bands of varying heights surround all miniatures. The scenes, however, are not well proportioned. The date of origin of the *Iliad* is uncertain, but the text on the recto of the leaves is in Greek uncial script characteristic of the fourth to fifth century.

Vienna Dioscorides or *Constantinopolitanus* (National Library, Vienna) is another ancient Greek illustrated text on science by the great Greek botanist Dioscorides of Anazarbos. It consists of 431 leaves each about 15 1/4 × 13 1/4 in. It is the earliest known codex with gold background. No illustrated Latin manuscript has survived from the early Roman period.

Vatican Virgil (Vatican Library) has 76 leaves, about 12 in. wide and over 12 in. in length. Its 50 pictures are uneven in quality but some of them are very well executed. The codex constitute one-sixth to one-fourth of the original manuscript. The main colors used are dark and light blue, light yellow, brown, green, red, pink, light

purple, orange, gray, white, black, and gold. Flesh has the color of brick red. Miniatures are of Roman origin. The text is in rustic capital of fourth or fifth century.

Roman Virgil (Vatican Library) has 309 square leaves of about 13 1/2 × 13 1/2 in., with 19 miniatures painted in gold, black, white, yellow, brown, purple, blue, green, yellow green, and red. The painting reflects a decadent classical style.

Alexandria, Antioch, and Rome were the important centers where Greco-Roman art flourished.

BYZANTINE ILLUMINATION

In A.D. 330 Constantine shifted his capital from Rome to Byzantium and renamed it Constantinople (presently Istanbul in Turkey). He also declared Christianity the state religion. Constantinople became not only the seat of the Roman empire or the new Byzantine Empire, but also flourished for over 1000 years as one of the great intellectual and artistic centers of the whole ancient world. In true sense, illumination developed in Constantinople around A.D. 500. The main components of the Alexandrian school and the Eastern heritage of the Syrian school centered in Antioch.

The first period of the fourth and fifth centuries is formative and marks the beginning of early Christian elements of rather pagan symbolism. At this time, books were in roll form and illustration was more common. The *Joshua Roll* (ca. A.D. 472, Vatican Library) is a good example of this period. Its origin, however, is debatable. It is written in the script of tenth century minuscule. Until 1902 it remained in roll form, measuring 35 ft. × 1 ft., but since then it has been divided into separate sheets and gathered into an album.

In the sixth century A.D., during the reign of Justinian (527–657), Byzantine illumination reached its first golden age, and became a Christian rather than East Christian art. Main features were the use of vellum in the form of codex comparable to the book of today, decoration of manuscripts of gospels with brilliantly painted ornamental designs, use of gold or silver lettering, superbly executed miniatures embellished with highly gilded backgrounds, angularity of outline, meagerness and elongation of form, and richness of costume, which indicated oriental influences. But very few manuscripts of this period could be preserved. The style and color combination of the period, however, are noticeable in mosaics and frescoes of Roman Churches of medieval times.

The period of iconoclasm (a movement against image worship due probably to Judaeo-Islamic influence) from 726–843 wrought havoc to the art of illumination. Precious illuminated manuscripts were destroyed and mutilated. The artists of this period substituted ornamentation for miniature, and flora, fauna, and geometric forms for figure paintings. In the second half of the ninth century

there were two divergent styles: those of the court, “aristocratic” or aulic, based on the sixth century Alexandrian Hellenistic pattern for dogmatic and liturgical canons; and the monastic, based on the Eastern manner of Syria-Palestine called “Cappadocia,” in which the illustration of contemporary life became more common. Revival of image worship in 843 brought about the return of figures to paintings, which gradually helped in producing the best miniatures of the Byzantine period.

The most glorious period of Byzantine art is from the tenth to the twelfth centuries, which can be called the age of brilliant miniaturists. *Paris Psalter* (Bibliothèque Nationale, Paris) of the tenth century is a good example in presenting freshness and brilliancy in life. *Vatican Psalter* (Vatican Library) of 1059 has rich miniatures of brilliant coloring. *Vienna Genesis* (National Library, Vienna), an illuminated manuscript, claimed to be of much earlier date, was actually produced later. Its decorative pattern, such as arcades surmounted by monsters, beasts, birds, vases, trees, plants, flowers, interlaced borders and crosses, became very popular in medieval Europe.

The most marked influences of the period could be seen in tessellated and mosaic pattern, interlaced fret work, or twining branches of gold or white over a background of variegated colors, which became a general style in Western Europe.

Byzantine art received a heavy setback by the Latin occupation of Constantinople in 1204, and it ended in 1453 when Constantinople fell to the Ottoman Turks. This was also the time when national styles of illumination were highly developed in Western Europe and also in the Orient. The influence of Byzantine artists was manifested in later works. The areas that were predominantly in the Byzantine sphere of influence were Syria, Palestine, Coptic areas, Armenia, Georgia, the Balkans, and Russia.

EUROPEAN WEST, SIXTH TO ELEVENTH CENTURIES

Western illumination, while it reflects a strong Eastern influence, developed its own original pattern, tendencies, and styles, which in a true sense were more decorative than illustrative. Three outstanding traditions of illumination, the Hiberno-Saxon, Carolingian, and Ottonian are noteworthy.

Hiberno-Saxon Illumination

The seventh and eighth centuries gave rise to the most outstanding schools of Hiberno-Saxon illumination, also called Celtic art. Main features of Celtic illumination are introduction of initials and margins, and full page designs with intricacy of interlacing spirals, zigzags, and ribbons that entangle animal and human shaped fancies, knots and other designs, all executed with a marvelous precision of

mathematical accuracy, delicate touch, and brilliant coloring. Irish illumination is decidedly oriental in execution and conception. The decorative schemes are more similar to the Arabic than to any other.

The best example of Celtic illumination is the *Lindisfarne Bible* (British Museum) written in the early eighth century in honor of Saint Cuthbert. Insular majuscule for initial letters and half uncial script for text are used. Figures show the influence of Byzantine models.

Another most outstanding work is “*Q*” *Codex* or the *Book of Kells* (Trinity College, Dublin). The 339 surviving leaves contain an incomplete Latin text of the gospels written in combination of uncial and round half uncial script. The ornamentation includes leaf and plant forms, zoomorphic forms, interlaced geometrical patterns, and curious figures. The use of lapis-lazulic blue, the unusual square punctuation marks, and introduction of vine foliage as a new decorative element suggest a later date than seventh to eighth century as usually assigned. No gold was used in *Book of Kells*.

Another example is the *Book of Durrow* of late seventh or early eighth century origin. It is in four colors, dark brown, brick-red, bright yellow, and green.

In Southern England, the Canterbury Scriptorium became an important center of illumination. Here the art was based on early Christian figural tradition in stiffly outlined forms and partly on the Hiberno-Saxon style ornamentation.

In the last decade of the tenth and early eleventh centuries an independent style of illumination flourished in England at Winchester. Borders with foliage in soft shades or in gold, and large initials were the chief characteristics of Winchester style. Later, Hiberno-Saxon art strongly influenced Western European illumination.

Carolingian Illumination

The flowering of Carolingian illumination began with the crowning of Charlemagne (Charles the Great, 742–814) as Emperor of the West in A.D. 800. Charlemagne’s court was the scene of great splendor where many cultures met and fused.

A large number of superbly illuminated purple codices of gospels and sacred texts were produced at the monastic and imperial scriptoria. Carolingian illumination reflects the influence of Byzantine art in the arcaded canon tables, brilliant miniatures, and lavish use of gold or silver in letters as well as illustrations on purple ground. Celtic style can be seen in large initial page designs, and the inclusion of exotic birds seems of Syrian origin. Miniatures represent historical themes. Carolingian illumination, however, shows a tendency to coarseness of workmanship and clumsiness of figure painting on purple vellum.

The Carolingian art flourished in Germany, France, and Italy. The main centers included Tours, Rheims, Aachen

(Aix-la-Chapelle), Metz, Fulda, Lorsch, and Hautvillers. *Otto Gospels* (John Ryland Library, Manchester) of the second half of the tenth century is a good example. It has a full page of decorative patterns in purple and gold and was executed at Cologne or Saint Gallen.

In the second half of the tenth century there was a great influx of Byzantine artists due to the marriage of Otto II to the Byzantine Princess Theophano in 972. The combined technique was an improvement in that facial expressions were more human and had better sense of proportion.

Important centers were the Benedictine Abbey of Reichenau; Regensburg, the seat of the Bavarian School of Illumination; Salzburg; Bamberg; Magdeburg; Trier; Mainz; the Monastery of Fulda; and the Scriptorium of Hildesheim.

ROMANESQUE PERIOD

The eleventh century marked the beginning of Romanesque style. The principal features were monumentality, growth of distinct national styles in art and architecture, religious fervor due to the crusades, large scale building of monasteries and scriptoria, and production of large bibles, psalters, gospel books, missals, biblical commentaries, particularly on the Apocalypse, and other liturgical and religious works, lectionaries, homilies, lives of saints, sacramentaries, and secular codices.

The Romanesque style had as its model the later Hiberno-Saxon and Ottonian as well as Byzantine works. Its main characteristics were elaborate decoration of initial letters ornamented with interlaced ribbons. Gold ground became more popular, and borders and backgrounds composed of a system of frames were used. Illustration directly related to the texts became very common.

During the Romanesque period the development of national styles of illumination in England, France and Low Countries, Spain, Germany, and Italy was notable.

England

The Romanesque or Norman period of the eleventh and twelfth centuries is the greatest in the history of English illumination, with Winchester, Canterbury, Durham, Westminster, St. Albans, Bury St. Edmunds, Hereford, Peterborough, and Croyland as the main centers. Fine bibles, psalters, missals, and liturgical books were the principal products.

The main features of Norman illumination were reflection of Romanesque style of architectures, Byzantine and Syrian influence in striking use of gold and heavy color, mushroom trees in the background, interlacing foliations and fantastic animals, and scenes illustrating the text of Hiberno-Saxon origin, elegant figures with elongated forms, and often full page illumination revealing Carolingian influence. The full page miniature and the stately and

monumental size are important features of the twelfth century books. The *Winchester Bible* (Winchester Cathedral Library) is a good example of this period. Originally it was in two, but is now in three stately volumes, and is generally considered the finest of the monumental bibles. It has beautiful miniatures, full page outlines of drawings, good proportion of figures, with rich and beautiful coloring in dark deep tones, deep blue-green historiated initials, human figures, plants, and luxuriant foliage.

France and the Low Countries

Two schools of illumination, Southern and Northern, developed in the eleventh century. The Northern School had the influence of the Anglo-Saxon while the Southern developed on Italian and Spanish models of illumination. The color scheme shows Mozarabic influence as practiced in Moorish Spain.

At the scriptoria of various abbeys in Paris, Rheims, and in Alsace and Lorraine, magnificently illuminated bibles, psalters, gospels, sacramentaries, lectionaries, homilies, lives of saints, and commentaries on holy books, as well as secular works, were produced. Illumination rather than calligraphic work excelled in ornamental draftsmanship. The color scheme included red ink with blue, green, or yellow backgrounds. The decoration had interlacings and coils, foliage, and panels of ornamental lettering. The human figure, however, is not well portrayed. Initials were done in gold and silver on a purple background. The decline of scriptoria of the great monasteries dates from the middle of the twelfth century.

An important example of the period is the copy of the *Commentary on the Apocalypse* (Bibliothèque Nationale, Paris). Its color schemes and decoration reflect the Mozarabic character of Spanish models. In the regions now known as Belgium a great number of huge bibles were produced. The best known is *Stavelot Bible* (now in the British Museum).

Spain

A new style developed by the Christians under the influence of Muslims in Spain is called Mozarabic art. Early Mozarabic manuscripts had primitive illumination consisting of ornamented colored initials, with green, yellow, and violet colors. Mozarabic illumination greatly influenced medieval art particularly in Spain, Italy, and Southern France. About 25 manuscripts of this period are extant and are known as *Beatus Manuscripts*.

Germany

In Germany and German speaking areas, the Ottonian tradition of illumination remained strong. Typical variations are productions of great bibles with illustrations of

tiny framed scenes, huge initials of gold, silver, and other colors, and arcaded canon tables.

The main features of German illumination of this period are artistic design of linear outline, fine drawings with rich and massive grouping of foliage presented in the ornamental initials of white foliated branch outlines in red on soft blue and green fields, and dignified border designs. Emphasis was also placed on artistic calligraphy. Initials became smaller but were exquisitely drawn; dragons and birds were often added to the intertwining stems and leaves to form effective head and tail pieces to the letters, and occasionally human figures were added as part of the decorative scheme.

Italy

Italian illumination had the influences of Byzantine, Carolingian, Ottonian, and Hiberno-Saxon elements. Illuminated manuscripts, produced at Benevento in southern Italy from the eleventh to the thirteenth centuries, consisted of long rolls of parchment or vellum. The color scheme contrasted light blue, pale-green fields with ultramarine or crimson background, on which orange-yellow or gold letters paneled with geometric patterns in red, white and blue, filled with intertwining white vine tendrils, stood in sharp relief. Decorative work was of high quality, although the historiated initials with portrait miniatures were flat, wooden, and generally monotonous.

GOTHIC PERIOD

The rise of Gothic art in the thirteenth century was supremely demonstrated in its architecture with pointed arch and stained glass, which eventually had its great impact upon the book decoration. The main feature of this period was the production of smaller books intended for individual or family use in large numbers. Large and bold characters were replaced by neat minuscules. Historiated initials became more popular. Full page pictures, common in the Romanesque period, became rare and were much reduced in size. Besides liturgical works, private devotional works such as the *Book of Hours* became very popular. In addition, many secular works such as histories, chronicles, and romances began to appear. Gradually, the interest of the monasteries showed a marked decline because of Cistercian disapproval of extravagant forms of illumination. The influence of glass painting became manifest in manuscripts. Interest in landscape and contemporary life became more apparent in painting, and the use of burnished gold leaf became more common.

Gothic initials had elongated terminals, from which sprang rich borders gradually surrounding the text on all four sides. The main part was first straight and rigid, called bar border, but gradually developed a trend toward

transforming the bar into a thin cylindrical rod adorned with rings and other ornaments.

Gothic illumination first flourished in France, and then in England, Italy, and elsewhere in Europe.

France

The rise of universities and the growing interest of abbots, kings, dukes, feudal lords, and rich merchants in books made Paris the main center of art, culture, and learning in Europe. Urban bookshops, traveling artists, and guilds of scribes, binders, and illuminators were organized and developed.

The main products consisted of psalters, breviaries, and especially Books of Hours, which were superbly illuminated. Contemporary scenes of knights, ladies, troubadours, and minstrels were depicted in the art, including a background of landscape with richness of color, abundant in gold. In the Grisaille technique developed in Paris, the picture is not fully painted. The color, in part pale semiluculent monochrome, creates a harmony between picture and script and transforms illumination into something foreshadowing painting and other graphic arts. The figures are on a colored ground and are faintly shaded and modeled in a cold gray so that they appear as if carved in relief against brocaded and tessellated gold grounds and bright colors.

The examples of this period are numerous, but some of the important illuminated manuscripts are *St. Louis Psalter* (Bibliothèque Nationale, Paris), which has a linear and supremely elegant style, and *Roger of Parmis Treatise on Surgery* (British Museum), which has fully illuminated pages in gold and colors.

In the late thirteenth and early fourteenth centuries richly illuminated books were in great demand by laymen. Illustrated books such as *Biblia Pauperum*, the *Legenda Aurea*, and *Speculum Humanae Salvationis* became very popular.

Paris also was the center of famous artists such as Honore and his son-in-law, Richard de Verdun, and Jean Pucelle, a pioneer in the study of nature, the invention of marginal drolleries, the exposition of traditional iconography, and in rendering buildings in perspective. Pucelle's works, *Belleville Breviary* (Bibliothèque Nationale, Paris) and the *Hours of Jeanne de Evreux* (Cloister, New York City) are good examples. His workshop dominated the first half of the fourteenth century.

Low Countries

Illumination in the Low Countries was of Northern French and Northern German origin. The principal characteristics were plain burnished-gold background, deep blue coloring paling toward the horizon, and natural landscape in the background.

The abbey scriptorium of Stavelot was very famous for its excellent illuminated works. Its chef d'oeuvre, a great two-volume bible, is a good example of the work produced there.

Zwolle Scriptorium in Northern Holland was famous for calligraphic ornament, the painting of the initial letters, and the decoration of the borders with flourished scrolls of penwork, neatly drawn and finely painted.

Flemish psalters of outstanding beauty and elegance were produced by the middle of the thirteenth century. The most famous, the *Maastricht Hours* (British Museum), measuring only $3 \frac{3}{4} \times 3 \frac{3}{4}$ in., represents scenes such as a fox shamming death, and three living and three dead kings.

England

England of the thirteenth and fourteenth centuries had two predominant traditions, Gothic and East Anglican.

The Gothic style had delicacy of drawing and refinement of taste with luxuriant decoration of bar borders and margins full of whimsical animals, birds, and creatures of fantasy. Human figures had a softer, more rounded and gracious contour.

The color scheme frequently used included deep rich blue, balanced by red and light green and lightly shaded with buff, gray, and pink. All psalters contained superbly illuminated initials, "B" for Beatus, and historiated initials. Spaces at the end of verses were usually filled in with pen designs in blue and red with flourishes, geometric patterns, or witty drawings of animals.

The main features of the illuminated manuscripts are their small size (sometimes like pocket books), firm, delicate draftmanship, and neat calligraphic script with ornamentation restricted to foliated initials in burnished gold and warm coloring at the beginning of each book.

The Abbey of St. Albans was a great center for the production of illuminated manuscripts. *Windmill Psalter* (Pierpont Morgan Library, New York) and *Tickhill Psalter* (New York Public Library) are some of its outstanding surviving examples.

Norwich was the center of East Anglican style. Its manuscripts have large borders, decorated with ornamental foliage interspersed with human figures, birds, animals, little grotesque armorial bearings, and the like. The principal characteristics are a rich and harmonious color scheme, with ornament in the design of frame borders, and initial decoration. A good example of this style is *Robert de Lisle* (British Museum).

Germany and German-Speaking Countries

In Germany, Byzantine and Romanesque traditions continued. But the Thuringian-Saxon School and the Benedictine monastery of Weingarten produced exquisite psalters; *Berthold Missal* is the chief product of the latter school.

The late thirteenth century Gothic style of Southern France influenced Germany. Austria also became important for its delicate pen drawings. In Bohemia, the Austrian and Italian influences could be seen in the Prague School, their main characteristics being soft, curling foliage, and fresh colored flowers. A detached initial "U," representing the Holy Trinity (National Gallery, Washington) is a good example of Bohemian style. This school influenced English illumination in the late fourteenth century due to the marriage of Charles's daughter, Princess Ann, to Richard II of England. Another work is *Passional* (University Library, Prague) with fine allegorical miniatures in water color. It shows architectural details in Gothic style. A copy of the *Golden Bull* (National Library, Vienna), the constitution of the Holy Roman Empire, is at its best in its style.

Italy

The Gothic style in Italy developed in the thirteenth century. In addition to liturgical works, the main products were law books and legal commentaries, mainly produced at the University of Bologna. Although the period had strong French Gothic influence, Byzantine influence also continued. The main features of illumination were conventional border ornament, long pointed leaves with lobes generally on one side only, cup shaped beads threaded on the wands and stems, and comical use of human, animal, and grotesque figures, such as a hare hunting a man, as can be seen in a small bible now in the British Museum. Fourteenth century illumination is like fresco or panel painting on a small scale, found in municipal accounts books.

In the middle of the fourteenth century English illumination came to a sudden end due to the plague. In the late fourteenth century, however, a new style of illumination on the model of the German School, particularly Rhenish or Bohemian, is noticeable. Its chief characteristics were independent borders with stem and leaves throwing off thin twisted tendrils with gold balls at the end, greater softness in the treatment of the face, depending more on use of brush than pen and pencil, a more harmonious color scheme, a more skillful use of architectural ornament, and the introduction of new forms of foliage and of a white scroll with sinuated edges, wrapped round the upright shafts of pillars or initials. Landscapes were presented in gilded ground, tapestried, or checkered backgrounds.

John Siferwas, a Dominican friar, is famous for his work, particularly his masterpiece the *Sherborne Missal* (Alawick Castle Collection, Northumberland).

FIFTEENTH CENTURY TO THE DECLINE OF ILLUMINATION

In the fifteenth century or during the Renaissance, illumination became a pursuit of professional artists patronized

by ruling kings, dukes, and the Papal Court, and developed as a true art. The painting was more real, depicting men and women of flesh and blood. The modeling of flesh became three dimensional, portraying a true feeling of life.

Luxuriously illuminated manuscripts were produced during this period. The main features were decorative frameworks and a transition from the miniature, with its three dimensional space construction, to the flatness of the empty ground of the page.

In this period illumination flourished most in Italy, France, and the Low Countries. Each region had its own distinct characteristics.

Italy

In Italy, calligraphy and illumination both flourished as independent arts. The use of humanistic script in manuscripts became more popular. The manuscript was regarded not only as a show piece but also as something that could be used by scholars; illumination began to be confined only to the frontispiece. Its main feature was border illumination, consisting of narrow gold bands in a rectangular frame interlaced with scrolls of vine tendrils in white, on grounds of alternating blue, green, and crimson. The border enclosed putti, animal forms, and medallions in wreaths of foliage. Sometimes human figures, heraldic or symbolic designs, or busts, were copied from antique models. Miniature painting was linked with monumental painting. In Florence, the cradle of the Renaissance, famous artists such as Fra Angelico, Botticelli, Lorenzo Monace, and Attavante degle Attavanti developed their own styles. The masterpiece of illumination of this period is *Lorenzo Hours* (Biblioteca Laurenziana, Florence) a small book of 4 in. × 6 in., with lovely borders with scrolls of foliage and flowers and rayed gilt disks painted on plain white vellum.

Another great work is the illuminated bible made for Borso d'Este, the *Borso Bible* (Modena Estense Library), a product of the Ferrara School of illumination, which is famous for its distinct character and elaborate margins. Sixteenth century Italy marked the decline of illumination, but the products of such famous miniaturists as Giulio Clovio are notable. Clovio attempted to translate the most monumental qualities of Renaissance frescoes into miniature. The *Book of Hours*, which he illuminated for Cardinal Alessandro Farnese in 1546 (Pierpont Morgan Library, New York), is a good example of his work.

France

In the fifteenth century, France saw the greatest flowering of illumination. Books of Hours were the finest and most numerous. Three great masters were Rohan Master, Jean Fouquet, and the painter of *Livre du Coeur d'Amour e pris* (National Library, Vienna). Rohan Master's art can be

seen in the *Grandes Heures de Rohan* (Bibliothèque Nationale, Paris).

The Limbourg brothers's (Pol de Limbourg and his brothers) *Très-Riches Heures* of the Duc de Berry (Musée Conde, Chantilly), which they left unfinished at their death, is a sumptuous codex. Every page has a luxuriant full border with brilliant title medallion miniatures and superb portrait pages.

Jean Fouquet of Tours spent his early days in Italy, and shows that influence in both panel and miniature painting. He was an artist of international fame in his own time. His illumination in the 47 preserved pages of *Hours of Etienne Chevalier* (Bibliothèque Nationale, Louvre; British Museum, Musée Conde) created miniatures which are elegant and show the influence of the Limbourg brothers.

The third important work, the *Livre du Coeur d'Amour e pris* was written and illustrated by King Rane of Anjou. The miniatures depict the spirit of late medieval chivalry.

In the Low Countries, Trounai, Ypres, Bruges, Ghent, and Brussels were important centers of illumination. Paintings in grisaille were also popular.

Germany

German illumination in the fifteenth and sixteenth centuries can be characterized by putty-colored border frames in which green and scarlet often appear. Franco-Flemish influence is very strong, as can be seen in a seven volume bible with richly illuminated border now preserved in Rome.

Masterpiece of the Glockendons, a prayer book executed by Albrecht Glockendon for the Duke of Bavaria (Biblioteca Estense, Modena) contains 41 full page miniatures and numerous colored initials on gold. Other rich illuminated manuscripts are those that were commissioned by the Emperor Maximilian.

The sixteenth century finally marked the end of illumination in Germany and elsewhere in Europe except for casual execution of religious books and invitation cards.

ISLAMIC ILLUMINATION

Islamic illumination developed from a modest beginning. The early art was purely calligraphic and centered around the development of script, style of writing, and beautification of letters. Then came decoration, first with the use of gold and then with colors. Early illuminated manuscripts basically consisted of Quranic texts and had no illustration or painting depicting any life, as they are not allowed in Islam. Illustrations and paintings were included later in secular works only. The art of miniature painting, which attained an independent pictorial composition, developed in Persia and strongly influenced Turkey and Mughal India.

Arabic script written from right to left became the main script of the Islamic world, and it played the same role as Latin in medieval Europe. It has five variants: Kufic, Naskh, Maghribi, Taliq, and Nastaliq.

Kufic (angular vertical) was named after Kufa in Mesopotamia. It remained the chief script of the Quran for over four centuries, and for about a century for general use. It was a most popular early script and is used even now for epigraphy. After the ninth century, letters evolved into distinctive ornamental style, were elaborately intertwined with shafts, and linked closely with the leaf scroller of the ground, and are usually called Kufic fleuri.

Naskh (round and cursive and later developed into calligraphic form) originally was the cursive form of Kufic, but it is generally said to have been developed by Ibn-i-Muqla in the early ninth century. Naskh became most popular for religious as well as secular writing. By the twelfth century it finally replaced Kufic. Now the Quran is universally written in the Naskh script.

Maghribi (round and heavy) is a variant of Naskh script, which became popular in Islamic West or Northern Africa. In Moorish Spain it was called institutional script, as it was used for both religious and secular works at Cordova.

Taliq (cursive) was developed in Iran by Hasan Farsi in the early tenth century and was used for popular writing. It became popular in Turkey by the name of "Diwani" or court style. Later on it became popular in India also.

Nastaliq (elegant and round with thick and thin strokes) is an Iranian variant of Naskh but quite independent and distinctive in style, developed by Mir Ali Tabrizi in the late fourteenth century. Nastaliq gradually became the main writing style in Iran and India for secular subjects. The best illuminated manuscripts in Iran and India are in Nastaliq script, except for Quranic text, for which Naskh script is universally used.

Style

Twelve different styles were developed from Kufic script by Ishaq bin Hammad in the early ninth century. They are: Tumar, bold letters for Quran and inscriptions; Sajalat, or Court style; Ohud, for deeds; Amanat, for agreement; Madih, for eulogy; Ghubar, the use of dots to give an impression of cloud, for beauty; Moammerat, for official deliberations; Dibaj, writing on silk; Murassa, ornamental; Hasan, elegant and thin; Riyash, or pictorial; and Bayaz, for documents.

In the late ninth century the famous calligrapher Ibni-Muqla (886–940) developed six styles: Thulth, or one-third, just like uncial script, was bold and was used for Quran and religious texts; Naskh, round and cursive, for religious text; Toqi, bold letters used for official statement; Riqa, for correspondence and accounts; Muhaqiq, book style used by scholars; and Rehan, thin letters used by ladies.

In the beginning, the calligrapher had to illuminate and rubricate, but gradually each of these functions was performed independently by the calligrapher, the illuminator, and the painter. Ink was made from soot and arabic gum, with vitriol or alum; pigments were prepared from gold leaf, powdered lapis lazuli, orpiment, yellow ocher and the like, again with the use of arabic gum.

Decoration included a title page, which always had double headings of the chapter and border medallions. Later, it became a fashion to include in the text the name of the calligrapher, and the date and place of production in a modestly worded tail colophon following the text at the end of the page.

Illumination, though still in fashion for Quranic texts, basically flourished in the Islamic world from the eighth to eighteenth centuries. The following periods and areas are important for developing their own distinctive styles of illumination.

EARLY ISLAMIC PERIOD

The Muslim era begins from September 13, A.D. 622. Most of the manuscripts, including the complete text of Quran and the letters of Prophet Mohammed (560–632), were written after this date. The earliest preserved Quranic manuscript is the one used by Hazrat Uthman, the third Caliph (644–656) at the time of his martyrdom in A.D. 656. It is now in the State Library, Tashkent, and a photocopy is in the National Museum of Pakistan, Karachi. It is on a broad parchment sheet written in large early Kufic letters. The earliest dated copy of Quran is of A.D. 784 (National Library, Cairo).

The earliest style of decoration developed in Mesopotamia, Syria, Northern Africa, and Moorish Spain.

In Mesopotamia, the earliest center was Kufa, where Kufic script originated. The Kufic writings of this period were thick and rounded, with short verticals and large horizontals. For decoration, gold was used, and later a few colors, more frequently natural or colored blue, violet or red, and black were also added. Illuminated pages at first had interlacing, foliate forms, and palmette scrolls outlined in brown ink. This style was common in Syria and Egypt.

MAGHRIBI SCHOOL

The term Maghribi or Western Islamic is used for Northern Africa and Moorish Spain. Syrian style of illumination had strong influence in these regions. Damascus in Syria, the capital of Umayyad Caliphs (661–749), had developed a distinctive style of writing which, unlike Kufic, was very close to Naskh. The same variant spread in Northern Africa, particularly in Spain where a fugitive, Umayyad

Prince Abdur Rahman I (756–788), laid the foundation of Moorish rule in Spain with his capital at Cordova.

MOORISH SCHOOL (756–1492)

In the whole of Maghrib (Islamic West) the calligraphic form has not been so well developed and refined as in the east, but the illumination on parchment in polychrome is exquisitely rich. The Moorish codices with arabesque work, executed primarily in gold and blue, surrounding the pages in variants, twining round the headings, and the marginal decoration are superb.

In the fourteenth and fifteenth centuries, Granada became very famous for its vivid color composition, and Alhambra style became an established model for embellishment of a codex. Some texts have free drawing of tree forms with their branches spreading across the text, and can be associated with Sicily in decorative pattern.

Examples of early illuminated Maghribi manuscripts are rare. There are some from the later period in Morocco and Tunis but they are not brilliant examples.

MOZARABIC ILLUMINATION

Under Muslim influence, a new style of book decoration was developed by Jews and Christians in Spain, generally called Mozarabic art. For example, Jewish illumination of *Exodus* (British Museum) shows a marked influence of Islamic style. The majority of the Hebrew codices from the tenth to fifteenth centuries were produced in Spain. The illuminations are executed in bright colors on a gold background. Besides religious manuscripts, there are also illustrated secular works, for example a finely illuminated fourteenth century copy of Avicenna's *Canon of Medicine* (Biblioteca University, Bologna, Manuscript 2197).

Christians in Spain were influenced by Moorish style, particularly in ornamentation of initials, as can be seen in *Beatus Manuscripts* produced in Spain, Italy, and Southern France.

FATIMIDE SCHOOL (909–1171)

The Fatimides, after defeating Aghlabides in Tunis in A.D. 908, became master of almost the whole of North Africa and first made their capital at Mahdiya near Tunis. A half century later they added Egypt and Syria, and founded the city of Cairo, which became one of the greatest intellectual centers of Islamic learning, particularly at the famous Al-Azhar University, which they founded. The Fatimides patronized the Nestorians and Jacobite Christians from Syria who were famous illustrators and illuminators. Many richly illuminated manuscripts of this period are found in the Cairo National Library and the Vienna

National Library. The style of writing is very close to Naskh, with rather heavy strokes. Illuminations are rich.

MAMELUKE SCHOOL (1250–1516)

After Fatimides, Ayubides (1169–1250) came into power, followed by Mamelukes or white slaves (1250–1516). Both of the later dynasties were of Central Asian rather than Turkish origin.

Mamelukes are noted for building great mosques and having inscriptions on walls and arches in majestic Tumar (bold) like Thulth, a variant of Naskh form. The large luxury Qurans in Tumar or Thulth, in gold on blue and brown ground, usually have title pages without text and are divided up geometrically into lattice or star shaped compartments with arabesques and palmettes. The chapter headings are generally in Kufic-like letters on a ground of leaf scrolls and surrounded by a border of interlacy. The illuminated texts of the Quran executed in this period and now preserved in great quantities (National Library, Cairo, and National Library, Vienna) are the best examples of Egyptian illumination.

ABBASIDE PERIOD (750–1258)

The Abbaside period was an age of great splendor in Islamic history. Harun-al-Rashid (786–809), of Arabian nights fame, and his successors, Mamun, Moatasim, and Matawakkil, were great patrons of art, learning, and scholarship. Charlemagne (742–814) had close cultural contacts with Harun. The court of Abbasi Caliphs at Baghdad witnessed the scenes of great cultural fusion. Baghdad, Samarra, Mousal, Basra, Nishapur, Dayar-i-Bakr, and Bukhara, were the chief centers of book art, particularly noted for the development of calligraphic styles. Two schools, those of Baghdad and Seljuk, were famous.

Baghdad School

The Baghdad School is noted for book art. It had the master minds of Ibn Muqla (886–940), Ibn Bawwab (991–1032), and Yaqt-al-Mustasemi (1221–1268), who developed various exquisite styles from Kufic and Naskh forms. The early form of writing was Kufic, and then ordinary cursive Naskhi, the most important features being the curving and elegant Thulth (bold) generally used for the Quran.

The Caliph Mamun-al-Rahid (813–833), son of Harun, patronized Manichian style from its founder, Mani, one of the greatest Iranian painters. The style had central Asian elements and was executed in Baghdad earlier than in Iran. Other famous painters were Abdullah Ibn al Fadhl and Yahya al Wasiti. Ornamentation included designs of

rosettes or palmettes, and the colors used were yellow, red, blue, green purple, and gold.

Not many illuminated copies of the Quran of this period have survived, but some are in the National Library, Cairo; Quran manuscripts of A.D. 883 and 890 are in the Bibliothèque Nationale, Paris. Another manuscript of A.D. 870 is in the Cambridge University Library.

Some of the old secular illustrated manuscripts such as *Kalila wa dimna* (fables of Bidpai), dated A.D. 1222, and *Maqamat Hariri*, dated A.D. 1237, are now in the Bibliothèque Nationale, Paris.

Seljuk School (1055–1256)

Seljuks were Turks. At the time of their appearance the empire of the Caliphate was vanishing. Art and learning flourished during the reigns of the great Seljuks Tughril Beg (1037–1063), Alp Arslan (1062–1072), and Malik Shah (1072–1092). They made Nishapur their capital. Besides Baghdad, other important centers were Raqqa, Ardh-Rome (Konya), Ray, and Kashan. The manuscripts available are of late Seljuk period of the twelfth and thirteenth centuries. Naskh style predominates in manuscripts, on metal works, and pottery. Decorations are executed in miniature style representing single figures, episodes from legends, and court scenes. The colors used are pink, olive green, cobalt blue, violet, brown, black, and gold on white or turquoise blue ground.

MONGOL PERIOD (1258–1500)

The Mongol period, though noted for ruthless wars, is equally famous for the development of sumptuous book art. Two important styles of writing, those of Taliq (cursive) and Nastaliq (round), were developed. Calligraphy and illumination attained highly rich and ornamental styles, with predominant influences of Chinese, Central Asian, and Iranian color composition. Two schools of illumination, those of Ilkhani (1258–1336) and Timuride (1387–1500), are important.

The glorious period of Abbasides ended with the sack of Baghdad by the Mongol invader Hilaku Khan (1256–1265) in 1258, Hilaku, or Hulagu, and his successors ruled Persia and part of Iraq, and were known as Il-Khanis. Tabriz, in Persia, and Maragha, just across the Eurphrates in Iraq, were their capitals. Ghazan (1295–1304), the grandson of Hilaku, accepted Islam, and while he continued the Abbaside tradition of illumination, he also encouraged the development of a new Mongol art.

Early Il-khani styles had Arabic influences, but gradually they developed their own pattern. The Naskh script, for example, became more angular and cursive and came to be known as Taliq. Illumination brought more Chinese and Persian elements in color scheme, and it became more figurative.

The earliest manuscript is that of *Manafeul-haiwan* (Morgan Library, New York), a bestiary executed by the order of Ghazan (1295–1304) at Maragha, with 94 illustrations. Miniatures show landscapes, clouds, plants, and peony flowers of Chinese origin.

Another manuscript is *Jameut-Tawarikh*, a world chronicle written in 1306 by Rashidal-Din, the Wazir of Ghazan and Uljaitun, at Tabriz. It has exceptionally rich illuminations with strong Chinese influence, particularly in costume, landscape, and the pale colors applied in washes. The manuscript has 55 miniatures superbly executed, of which a few have survived and are preserved in the Edinburgh University Library and in several private collections. Smaller copies of *Shah Nameh* (Book of King) of Firdausi (935–1010) are illustrated at Tabriz in 1320, and a few manuscripts are preserved in the Kofler-Truniger Collection, Lucerne, and in the Vever Collection, Paris. The pictures are placed in strips between the text with figures, costumes, and bright colors. Shiraz, next to Tabriz, was famous for illumination, but its work is less elaborate. Painting is generally in black outline on red or ocher background, with additional colors in blue, red olive, green lilac, and gold.

Ahmad Musa is regarded as one of the greatest artists of the Ilkhani School.

Timuride School (1386–1500)

The Timuride School is noted for an extraordinary artistic productivity and quality of illumination. Timur Lang (1335–1405), the founder of the Timuride dynasty, was a great conqueror and lover of art. He invaded India, Iraq, and Turkey and made himself the unchallenged ruler of Central and Western Asia. He brought artists from Baghdad and Tabriz to his capital at Samarkand. Some of the famous artists were Abdul Hayee and Junaid from Baghdad and Mir Babar Ali (1330–1404), the originator of the famous *Nastaliq* style, from Tabriz. Unfortunately, no manuscript of this period survives, except inscriptions on walls and frescoes.

Herat

Shah Rukh (1404–1447), one of the younger sons of Timur, and his own sons Baisunkur Mirza (1399–1433) and Ulugh Beg (1447–1449), beautified their capital, Herat, which became one of the greatest centers of illumination. Baisunkur was a great bibliophile. He founded a library and the Academy of Book Arts, which included 40 calligraphers, painters, illuminators, and miniaturists. Famous artists like Khalil; Jafar Baisunkuri; Abdullah, son of Mir Ali, and his pupil, Mawlana jafar Tabrizi, chief of 40 copyists; and a host of others were at his academy. Most of the masterpieces of the Timuride period were produced at Herat during the time of Shah Rikh, Baisunkur, and later, during the time of Sultan Husain Mirza.

A beautiful copy of *Gulistan* (Rose Garden) of Saadi (1184–1292) is preserved in Chester Beatty Library, Dublin. *Shah-Nameth* (Book of Kings) of Firdausi, elaborately illuminated in polychrome, is dated Herat, 1430, and is in Gulistan Museum, Tehran. *Fables Kalila and Dimna*, ca. 1420, Herat, is in the Gulistan Museum, Tehran.

Notable features of the Herat School are delicate rendering of figures, Iranian landscape with high horizon, and spongy mountains. Naturalistic plants and ornaments are derived from China, and are combined with birds and animals. Color combination shows Chinese influence, but is vivid and harmonious.

Shiraz

Another famous center of illumination that had a longer tradition than Herat was Shiraz, the capital of Ibrahim Sultan, son of Shah Rukh. Two styles of writing, Diwani (official) and Dashti (Tughra script) were developed. Some of the very superbly executed works extant are three copies of *Khamasa Nizami*, magnificently illustrated in 1444, now in John Ryland Library, Manchester; Royal Asiatic Society Library, London; and in Victoria and Albert Museum, London. The usual feature is that texts are on main and on border while pictures are between the texts. *Shah Nameth*, a finely executed copy in the Gulbenkian Collection, Lisbon, is a good example. A very fine copy of *Khamasa of Nizami* is in the Museum Dahlam, Berlin.

The main features of Shiraz style are cooler, lighter, but pale gold color scheme with dark blue ground. *Transoxiana*, the capital of Ulug Beg, son of Shah Rukh, was also an important center, but had the strong influence of Herat style.

The most prominent period of illumination flourished under Sultan Husain Mirza Bayaqara (1458–1505) at Herat, the last of the Timuride Sultans, Bihzad, Sultan Ali Meshadi, and his teacher Mawlana Azhar, the three versatile artists of their time, were at the court of Sultan Husain Mirza and were equally patronized by Mir Ali Sher Nawai, a great poet, musician, and painter. The Wazir of Sultan Husain was also a great patron of these artists.

The chief characteristics of this period were grace and elegance and a larger freedom of movement, gold, and brilliance in range of colors.

PERSIAN ILLUMINATION (1502–1736)

Shah Ismail, the founder of Safvide Dynasty, and his successors were great patrons of art, architecture, and learning. The period of Safvide rule over Iran for over 200 years, from 1502–1736, is the most glorious in the history of Persian illumination. Tabriz and then Isfahan became the centers of art. This was an age when the quality of the work depended very much upon the fame of the artists, and the fame of the artists of the Safvide

School was such that their works became models for Turkish and Mogul miniatures.

Safvide School

Tabriz, the new capital of Shah Ismail (1510–1524), once again became the leading center of book art. Shah Ismail appointed Kamaluddin Bihzad (ca. 1440–1536), a great calligrapher and artist, director of the Royal Library.

Bihzad had previously worked at Herat under the patronage of Sultan Husain Mirza, the last of Timurides, from 1470–1506. After the defeat of Timurides by Shaibanides in 1507, Bihzad remained in Herat and worked for Uzbek Sultan Shaibani Khan (1500–1510). But when Shah Ismail Safvi conquered Herat in 1510, Bihzad moved to Tabriz.

Bihzad built up a famous school of court painters at Tabriz and organized works separately for copyists, painters, gilders, margin drawers, gold mixers, gold beaters, and washers of lapis lazuli. Bihzad trained a good number of gifted pupils who continued his tradition at Herat, Bukhara, Tabriz, and Shiraz. Among his famous disciples were Qasim Ali Mirak, Shaikh Zadeh Mahmud, Abdullah, and Sultan Muhammad Nur.

Illuminated manuscripts of Bihzad are very few. The most artistic works were executed for Shah Tahmasp (1524–1576), one of the famous among them being *Shah Nameh* (British Museum). It contains 285 miniatures, some of them by Bihzad. *Khamasa Nizami* (British Museum) is also a richly illuminated copy. *Bustan of Saadi* (National Library, Cairo) has six miniatures by Bihzad, four of them signed. A copy of *Khamasa Nizami* (British Museum) illustrated by one of Bihzad's pupils, Qasim Ali, generally called Mirak, contains 16 beautiful miniatures. There are a large number of miniatures, now preserved in single leaves in various important libraries, art galleries, museums, and private collections in Europe and America, but the majority of them are in the Gulistan Museum, Tehran.

The characteristics of the Bihzad School are painting of borders in water colors in several tones of gold with a cool color scheme of blue, gray, and green, around a text of fine calligraphy. Later, Sultan Muhammad and Ustad Muhammadi employed pure wash technique in painting without any reference to a text. The other technique was the use of brush or red pencil, which became very popular during the time of Shah Abbas when he was at Qazvin.

Shah Abbas (1587–1629) made Isfahan, his capital, the center of decorated palaces and mosques. He established an academy of arts and employed leading artists of the time. The most famous were Mir Imad of Qazvin (d-1615), a master calligrapher, and Riza Abbasi (1587–1629), a great artist. Shafi Abbasi (son of Riza Abbasi), Muin, Yousuf, and Mohammad were other gifted artists.

The main work of Riza Abbasi is Nizami's *Khusrau and Shirin* (Victoria and Albert Museum, London). A large number of his signed paintings are preserved in the Tehran Museum. His style can be characterized with his

keen observation of life, and use of green, light blue, black, and gold colors on pale ground, with curves and short strokes in calligraphic form.

By the end of the seventeenth century a decline in Persian painting began. Shah Abbas II (1642–1667) tried to check it by sending some artists to Rome, but this admixture of foreign style finally finished the originality of the great art of manuscript painting in Iran.

TURKISH ILLUMINATION (1451–1900)

Ottoman Turks, as long as they had their capital at Konya, had Mongol-Persian models before them for book decoration. But after the conquest of Constantinople by Sultan Muhammad in 1453, a preference for Byzantine style developed. Therefore, European artists, along with Persian, were employed.

Characteristics of Turkish calligraphy and illumination are use of Naskh as standard script for religious works, development of Diwani, a variant of Naskh as official script, and use of Tughra, or decorative signature of the reigning Sultan with three long uprights and a large sweeping loop to the left. Production of finely executed texts of the Quran in pocket size became very popular. The color scheme included blue, black, and gold.

Turkish book art, however, remained essentially Persian in style and execution. The decline began toward the end of the seventeenth century.

Among famous calligraphers and artists who were either Turks or came to Turkey from other places were the following: Sanaullah of Brussa, a poet and a painter who worked under Murad II (1422–1451); Bellini, an Italian painter, who also trained Prince Ahmad and worked under Sultan Mohammad (1430–1481); Osman; Hyder; and Shah Kuli and Wali Jan of Tabriz, who were at the court of Sulaiman the Magnificent (1520–1566).

There is a large stock of illuminated manuscripts in the rich libraries of Turkey, but unfortunately all of them have not yet been explored.

MOGUL MINIATURES (1525–1707)

Mogul emperors were great lovers of art and architecture. The Mogul period is noted for the production of richly illuminated works usually called Mogul miniatures. There was no tradition of manuscript painting in India before the Moguls.

Babar, the first Mogul emperor of India (1525–1530), had remarkable talents. He wrote a vivid account of his life in Tartar language, *Tuzak-i-Baburi*, which is now among the classics of the world. He collected finely illuminated books, several of them now preserved in the princely collection of Alwar State. One painting depicting a sea fight, said to have been in the album of Emperor

Jehangir, is now in the State Library, Berlin. Babar attracted artists from Bukhara who introduced Bihzad style and cooler gouache tone.

Humayun (1530–1556), while in exile in Iran for 10 years, met the two leading artists, Khwaja Abdus Samad Shirazi and Mir Sayyed Ali at the court of Shah Tahmasp in Tabriz. Both were invited to Kabul and then to India to supervise the illustration of *Amir Hamza*, which is said to be the work of 50 painters and was completed during the reign of Akbar. It contains 1400 paintings on linen pages 22 in. × 28 in. Its leaves are now scattered in the libraries of the British Museum, National Library, Vienna, and Metropolitan Museum, New York. The completion of *Amir Hamza* marks the beginning of the Mogul School of miniature painting in India.

Akbar the Great (1556–1605) made Fatehpur Sikri his capital and built palaces decorated with mural paintings, executed by Iranian and Indian artists. While the Persian influence of Bihzad, Mirak, and Sultan Nur was strong, a new influence of Indian national style also took a firm root during his reign. Akbar established an Academy of Arts and employed 100 painters, the majority of them being Hindus. The work of all the painters is said to have been submitted to him every week. Akbar imposed his own ideas and themes upon the artists, but he also accepted the ideas of Hindu painters who introduced Hindu legends and religious epics. One of the best illuminated manuscripts of this time is the *Mahabharata* (Razm Namah), containing 169 miniatures, and now preserved in Jaipur. The execution of this sumptuous volume cost £40,000.

Some of Akbar's famous artists from Kashmir, Gujrat, and Punjab were Dharam Das, Sanwlah, Shankar Lal, Sur Das, Nar Singh, Mukand and Govardhan, Daswanth, Manohar, and Khem Karan. A good number of them were pupils of Khwaja Abdus Samad. The principal characteristics of their works were gradations of tone and effects of light and shade with atmospheric landscape and perspective and modeling in faces and costumes.

Jehangir (1605–1628) intensified painting, although his interest in illustration lessened. Artists were required to be more realistic and to describe court life, receptions, and audiences, festivities, hunts, and polo tournaments, and to chronicle noteworthy episodes from the life of the ruler. He liked western paintings and introduced them to his artists. Mansur, Murad, Manohar, and Abul Hasan (son of Riza Abbasi) were some of Jehangir's famous painters.

Shah Jehan (1628–1658) was a great calligrapher. Portrait art and ceremonial group painting received greatest attention during his reign. Famous artists of his time were Mohammad Fakirullah Khan, Mir Hashim, Bichitr, Anup Chhatar, and Sayed Amir Khan. Abdur Rashid Dailami, nephew of Mir Imad, also came from Isfahan. He was tutor of Dara Shikoh and also the founder of the Indian School of Calligraphy.

Aurangzeb (1659–1707), the last of the great Mogul emperors, was himself a calligrapher and wrote the Quran

for himself and for the princes. Being an orthodox Muslim, he discouraged painting and turned out the court painters, who then took refuge at the court of nobles and rajahs. This princely patronization to artists gave birth to a native style of painting, usually called the Rajput School of Painting.

Rajput School of Painting

Under the influence of the Mogul School of painting the Rajput School was developed. The same Hindu artists who had worked at the Mogul courts, along with their pupils, developed the Rajput style.

Characteristic features of the style were depiction of themes and ideas from Hindu religion, and epic, folklore, and cultural mode of life, which were more romantic and musical. The colors most frequently used were bright red, blue, and gold.

There are two predominant styles of the Rajput School, those of Rajasthani, covering Rajputana and Bundel Khand, and Pahari, covering Kangra, Basohli, Guler, and Jammu. The best examples are the scenes portrayed from *Krishna Lila* and *Nala Damyanti*, both of eighteenth century Kangra School.

The nineteenth century marks the total decline of illumination due to lack of princely patronage and also the vanishing skill of the artists.

Impact Assessment of Cultural Institutions

Sara Selwood

Department of Cultural Policy and Management, City University, London, U.K.

Abstract

In the United Kingdom, and in England in particular, concern with the “impact” of cultural institutions, cultural activities, and cultural policies has grown exponentially. Prompted by the government’s requirement for greater accountability within the public sector and its desire to implement evidence-based policy, this has particularly affected organizations in receipt of public funding. In the United Kingdom, these include the majority of cultural institutions.

This entry considers the context within which a preoccupation with the “impact” of cultural sector institutions came about. It examines the background to the introduction of the impact assessment of cultural institutions, the requirements made of them, and the impacts considered desirable for them to exert. It explores some of the difficulties of assessing those impacts, including definitions, approaches, and the problematic relationship between assessment and advocacy. The entry closes with a discussion of developments of impact assessment within the cultural sector. The principal focus of this entry is museums in England.

INTRODUCTION AND BACKGROUND

Since the 1997 general election, when New Labour came to power, the ways in which cultural policy in the United Kingdom have been articulated, disseminated, and assessed have been transformed. Prior to this, cultural policy was, to all intents and purposes, implied by the actions of such agencies as the former Museums & Galleries Commission and Arts Council of Great Britain. Despite being directly funded by government, these organizations tangibly operated at “arms’ length” from it. Indeed, it has been suggested that they functioned in what was, effectively, a “policy vacuum.” At best, the successive government departments responsible for funding the cultural sector reviewed current provision, sought to improve the management of advisory and funding bodies, and promoted examples of best practice. Performance measurement was generally considered inappropriate for cultural provision and was effectively steered clear of.

The requirement to evaluate policies and performance in the public sector was initially recognized by the Conservative government’s Financial Management Initiative of 1982. This called for greater efficiency, effectiveness, and “value for money” at central and local government levels—demands which were largely implemented through the National Audit Office and the Audit Commission both of which were established in 1983. The former was responsible for reporting on public spending programs in England, Scotland, and Wales; the latter for auditing and examining the management of local authority auditing in England and Wales. While neither body was, or is, specifically responsible for cultural services—museums, galleries, and the arts, nevertheless, fall within

their remits and are subject to the philosophy which they represent.

At this time, the museums sector had almost no measures to assess its success or progress except for the most basic indicators of attendances, budget size, staff size, etc. From the late 1980s various initiatives were introduced in an attempt to introduce a more sophisticated degree of performance management for national and regional museums and galleries including a registration scheme based on minimum standards and intended to provide an assurance of quality and professionalism.^[1]

Once in government, Labour insisted on greater accountability than previous Conservative administrations and emphasized the delivery of evidence-based policy making by central, regional, and local government. In that context, the question, “what works?” became a reference point for designing new policies and measuring performance. Analysis and the use of evidence were prescribed as core skills within the civil service.^[2–4]

The establishment of the Department for Culture, Media and Sport (DCMS) in July 1997 was marked by responsibility for cultural policy strategically being “reclaimed” by central government. By 1998, it had made it clear that cultural institutions’ increases in funding, and specially earmarked initiatives for the sector, were designed to meet the Department’s expectations and would directly influence the sector’s development.^[5] Predicated on the assumption that cultural provision is instrumental and can deliver on government objectives, DCMS’s “sponsored” (or subsidized) bodies have been required to commit to agreed targets, specified through a series of linked agreements which cascade down from the Treasury. Not only did the arts and culture become subject

to the same policies and regime of impact assessment, but they were all committed to achieving cross-government objectives which were intended to achieve broader economic and social policy aspirations. It was assumed that the impact of their particular contributions could be assessed (this is explored in Selwood^[6]).

Museums, which are the focus of attention in this entry, have been particularly close to DCMS's heart. They account for about a quarter of its total grant in aid and, therefore, carry considerable responsibility for delivering on the government's objectives. Indeed, from 2000 onward the Department has specifically credited museums with stimulating economic impact; creating employment; stimulating the development of ancillary services;^[7] tackling social exclusion;^[8] contributing to social and environmental impacts through transformational projects;^[9] and playing a part in the well-being of local authority areas.^[10] It has also referred to them as "centres of social change" and "learning."^[11]

Against a background of DCMS's interest in monitoring "outputs" and "outcomes" against its "investment" and its increased scrutiny of the performance of subsidized organizations, this entry considers the impact assessment of cultural institutions, museums in England in particular. It comprises four sections:

- The first section describes the requirements made of cultural institutions, and the kind of impacts that they are expected to exert;
- The second considers some of the difficulties of assessing the impact of cultural institutions;
- The third section comments on developments in thinking about impact assessment within the cultural sector; and
- The fourth, and final, section concludes with some observations.

Given that they share the same policy regime, both the arts and culture are occasionally referred to in this entry.

THE REQUIREMENTS OF CULTURAL INSTITUTIONS

The Department for Culture, Media and Sport's pledge that its sectors would deliver on a multitude of central government agendas was set out in its strategy document, *A New Cultural Framework* (1988) and its first annual report. This described its aims as being

... guided by four central themes: the promotion of access, for the many not just the few; the pursuit of excellence and innovation; the nurturing of educational opportunity and the fostering of the creative industries, which provide a growing proportion of Britain's employment

and wealth... aims which resonate across every other department of Government.^[12]

This section considers the application of those themes to the cultural sector and the instrumentalist values with which it became associated.

Although it has been argued that many museums were already committed to a community-based agenda, the Department incentivized the wider cultural sector's engagement through a combination of increases in funding and formal requirements. As Labour's first Secretary of State for Culture, Media and Sport, Chris Smith, put it, public funding would no longer to be regarded as

... 'something for nothing'. We want to see measurable outcomes for the investment which is being made. From now on, there will be real partnership with obligations and responsibilities.^[13]

As the Treasury's guidelines for departmental bids to the 2004 Spending Review made clear:

In principle, all spending decisions should be supported by evidence, demonstrating that the money being spent will achieve the desired effects as efficiently as possible.^[14]

Smith later admitted that this kind of climate demanded a particular kind of response from government departments:

Spare a thought... for the poor old Minister, faced with the daunting task of getting the increased funding out of the Treasury to start with. The Treasury won't be interested in the intrinsic merits of nurturing beauty or fostering poetry or even 'enhancing the quality of life'. So I acknowledge unashamedly that when I was Secretary of State, going into what always seemed like a battle with the Treasury, I would try and touch the buttons that would work. I would talk about the educational value of what was being done. I would be passionate about artists working in schools. I would refer to the economic value that can be generated from creative and cultural activity. I would count the added numbers who would flock into a free museum. If it helped to get more funds flowing into the arts, the argument was worth deploying.^[15]

These comments demonstrate the values that DCMS was encouraged to assume and the way in which it promoted the cultural sector within the wider political economy. Such political expediency set the tone for assessing the impact—or rather, the impacts of cultural institutions. Public subsidies were ostensibly invested in culture for any number of reasons—to reduce the incidence of social exclusion; contribute to education to encourage social regeneration; create destination locations; boost employment in service industries and inward investment in cities. But, in return, cultural institutions were obliged to provide evidence of how effective their contributions were.

Assuming that cultural institutions were making a difference was one thing, but quantifying, if not qualifying, the precise impact of such cultural institutions' effectiveness was another. As one arts minister explained: "I know that Arts and Culture make a contribution . . . but I don't always know how to evaluate or describe it. We have to find a language and a way of describing its worth. It's the only way we'll secure the greater support we need."^[16]

DIFFICULTIES IN ASSESSING THE IMPACT OF CULTURAL INSTITUTIONS

The model of accountability established by DCMS suggests that the relationship between policy, implementation, the delivery, and effectiveness of outcomes was highly determined as well as relatively simple. It assumes that the impact of various forms of cultural provision can be identified and quantified through the collection of "evidence," defined—"the end result of a complex analytical process beginning with the collection of raw data" (Table. 1). Indeed, for DCMS, an enhanced understanding of impacts was part of a virtuous circle in which the gathering and use of evidence would ensure that policies had maximum effect on key priorities and delivery targets.

However, DCMS's model conceals a number of difficulties which were not easily resolved and which, 5 years on, remain problematic. These include defining "impact"; the creation of objective and robust approaches to its measurement; and, the relationship between evidence and advocacy (for a more detailed discussion of these issues, see Selwood^[17]). These are addressed in the following paragraphs.

Definitions

The term "impact" is often used synonymously with "output" and "outcome." But in differentiating between these terms, "impact" has been defined as

. . .the effect of the outcomes on the environment. . . using that term very broadly to include people and society at large - and is usually in the long term. An example here

Table. 1 DCMS's understanding of the relationship between raw data and evidence.

Raw data	whether counted or measured once codified, checked and systematically set out/tabulated >
Information	which in turn when focussed on a particular set of hypotheses/policies yields >
Analysis	which when weighed, reviewed assessed and subject to professional judgement and scrutiny becomes >
Evidence	on the impact of a particular hypothesis, policy/ programme/or projects

Source: DCMS.^[18]

might be the growth in literacy (or even improvements in mental well-being) as a result of reading library books.^[19]

By comparison, outputs are

. . .the things that the organisation produced. They might be book or videotape issues, reference questions answered or seats occupied by readers. Very often, measurement consists of counting the number of outputs produced.

And outcomes are ". . .the short to medium-term results of applying outputs. The number of books read might be an outcome of book issuing."

Approaches

There have been a number of criticisms of impact assessments of cultural institutions, not least by DCMS itself. These stem from the early 2000s when the Department's systems of performance management were new. They pertain to the relative absence of hard evidence on cultural institutions' impact on tackling social exclusion: "Demonstrating the impact of activities to combat social exclusion is not easy, and it may be some time before the benefits are fully evident."^[20] The lack of robustness of the evidence on cultural activities generally in relation to wider social and economic policies was also criticized. Beyond DCMS's immediate funding stream, gaps in local authorities' cultural services' evidence-base were identified—stories about the performance of cultural services tended to be based on anecdote "rather than hard evidence through monitoring and evaluation."^[21]

The quantitative data collected was described as "patchy, inconsistent, and incomplete." According to conventional wisdom, this was not only regarded as inadequate but as inappropriate for evidencing the sector's contribution toward the achievement of the government's learning, access, inclusion, and economic development agendas. Acknowledging this, DCMS regarded quantitative evidence as proxies for qualitative outcomes. Thus, opening hours were interpreted as "a good measure of the availability of the collections for access"^[22] and numbers of repeat visits to museums as indicative of the likelihood that visitors' quality of life was being enhanced. But emerging research^[23] suggests that habitual visiting may be more indicative of visitors' dogged pursuit of personal interests than their satisfaction with particular venues.

Although data collection is becoming more sophisticated (for the most recent advice to DCMS on its museum performance indicators see Morris Hargreaves McIntyre^[24]), this has not detracted from the need for the cultural sector having to construct an increasingly more robust "evidence" base. Yet, the collection of data still emphasizes "the quantitative in a field where qualitative assessments have been regarded as central"^[25] and although impact is logically only discernable over the long-term, the government's

system of performance measurement, driven by biennial funding reviews, militates against this.

There are no cheap thrills in art, but there are real thrills. They come slowly, gradually, over years and as a result of effort. How do you market such an unappealing message, which happens to be the real message of the arts, the core—to use the market-speak—of their ‘Unique Selling Proposition’?^[26]

Thus, DCMS’s agencies’ habit of collecting short-term “evidence” on “new audiences” (as determined by the funding cycle) is likely to be relatively meaningless.

Reviews of the available evidence on the social impact of cultural projects have covered meta-analyses and critiques of single studies (see, for instance, Wavell et al.^[27]). The consensus is that much of the evidence presented is insufficiently robust for a variety of reasons including the non-substantiation of claims; the antagonism of cultural institutions towards the collection and use of data; the fact that projects have limited jurisdiction and limited potential to influence outcomes; the lack of robustness of the methodologies used; the quality of evidence gathered and a failure of reporting of methods; the difficulties of attributing causality; and the preponderance of short-term, as opposed to long-term, evaluations.^[28] More recently, issues of sustainability have come to the fore.

A prevailing theme has been economic impact. The assumption that various forms of culture are economically significant informs any number of policy papers published by DCMS, its agencies, regional bodies, and local authorities.

Culture, whether as a central part of a regeneration initiative, or as a substantial component of a broader programme, can play a distinctive role in bringing economic benefits to an area. It does not just bring direct economic improvement by providing employment and generating revenue, but can have a wider economic impact on the general prospects of an area by making it a more desirable place to live and work, and, subsequently, for businesses to invest.^[29]

Although DCMS initially regarded museums as being of marginal economic importance in terms of wealth and job creation,^[30] by January 2005, the Secretary of State for Culture, Media and Sport insisted that “Museums and galleries are . . . major employers and an important part of the economy.”^[31] And although the case for investment in museums on the basis of their impact on tourism, education, or the economy had apparently already been won,^[32] the commissioning of economic impact studies remains standard practice.

While it might be supposed that economic impact studies provide neutral assessments of the economic consequences of specific strategic interventions and that they provide evidence for future planning, they are primarily

recognized as a lobbying and advocacy tool. It was not by chance that Tate Modern celebrated its first and fifth birthdays by publishing an economic impact studies^[33–35] or that the National Museums Directors’ Conference (which represents the leaders of the U.K.’s national museums and galleries) thought it appropriate to commission major reports on their collective economic impact in anticipation of government’s spending reviews.^[36,37]

However, economic impact studies of the cultural sector are considered contentions and a considerable, specialist critical literature exists on the subject. (There is insufficient room here to review the literature. Readers are, therefore, referred to Reeves.^[38]) Direct impacts are considered at personal, community, local, regional, and national levels; indirect impacts, at ancillary levels (e.g. suppliers, restaurants, and accommodation) and in relation to the “wider community.” Sometimes economic impact is calculated through analyses of inputs and outputs, although more sophisticated theoretical applications include cost-benefit analysis; hedonic pricing; travel cost; contingent valuation; multipliers; displacement; and isolating the many variables that contribute to the impact of any activity or group of activities.

Highlighting the shortcomings of impact studies, of course, runs counter to the desire of DCMS and its agencies to report positive and demonstrable benefits, and to defend the sector against criticisms that it is not fulfilling the task it set itself.

Advocacy

From the outset of New Labour’s project to assess the impact of cultural institutions, critics have suggested that

The evidence, such as it is and it is limited, seems to indicate that museums have had really very little impact on their communities. No research results are available that prove that museums have an impact upon the problems of social exclusion.^[39]

Moreover, the political neutrality of “evidence” and, by extension, assertions of impacts, have often been contested. A fundamental reason for this is that evidence of impacts tends to be conceived positively, not least in terms of advocacy.

Evidence provides the proof of our ‘case’—whatever that case may be. It should, for example, prove beyond contradiction that investment in museums, libraries and archives will deliver social, educational, economic or political benefits on a scale that clearly makes investment highly attractive to government, a lottery distributor or some other funding body.^[40]

Over the past decade, the default among DCMS’s agencies has been to commission impact studies—especially in

anticipation of biennial Spending Reviews. Guided by the government's continuing commitment to social and economic aspects of the nation's well-being, these exercises are invariably intended to present the best possible evidence on effective activity.

But since DCMS's evidence-base primarily depends on data provided by institutions with obligations determined by their funding, distinguishing between advocacy-inspired research and objective social science enquiry is of fundamental importance. It is hardly surprising that those agencies, whose *raison d'être* is to promote the subsidized cultural sector and whose objective is to increase their funding, should be most interested in findings likely to serve their institutional goals. Indeed, in Britain, cultural institutions such as Museums, Libraries and Archives (MLA) Council and Arts Council England make no apology for their interest in research that fuels advocacy.^[41] In a bureaucratic culture encouraged to pursue evidence-based policy, it has been suggested that what agencies actually produce is "policy-based evidence."

The pursuit of advocacy obviously imposes severe restrictions on the kind of research conducted, if not what is published and disseminated. Cultures of advocacy tend to lead to biased reporting.^[42] For example, DCMS has consistently celebrated the national museums' success in attracting increased audiences since the introduction of free admission for all in December 2001. It has claimed that "the national museums are giving millions of people the opportunity to be stimulated, educated and inspired"^[43] and that "Free admission has democratised the nation's treasures making them accessible to all."^[44] But early objective and careful scrutiny of the data suggested that that while attendance was increasing, the most significant rises in visit numbers were among those who had always been well represented in museums and gallery.^[45] Moreover, subsequent analyses of attendance data reveals that it is not possible to tell how many more people from lower social groups, for whom this policy was designed, have attended museums and galleries as a result of free admission.^[46]

DEVELOPING THE IMPACT ASSESSMENT OF CULTURAL INSTITUTIONS

Assessing the impact of cultural institutions has been subject to issues of definition, methodology, and advocacy. But, underlying this has been a more fundamental uncertainty about the appropriateness of even attaching instrumental value to cultural institutions and products.

It appears that even as the former Secretary of State for Culture, Media, and Sport was putting a system of performance indicators in place to measure the impact of cultural institutions, he was aware of several drawbacks:

The first is that it ignores the fundamental life-force of the cultural activity that gives rise to the educational or

economic value in the first place. (Not, I hasten to add, that there is anything wrong in hailing the value of the educational or economic impact of culture; culture can be profoundly important for a fulfilling education and for a flourishing economy; it is simply that these should not be elevated above the innate value of the art of itself.) The second drawback is that any measurement of numbers, quantity, or added value by figures is necessarily going to be inadequate.^[47]

As this section reveals, such reservations are affecting changes in attitudes toward the impact assessment of cultural institutions.

Over the years, cultural institutions have accounted for themselves in relation to expectations of policy. Broadly speaking, they have described their putative contributions to employment and improvements in health and education, crime reduction, the strong communities, the economy and the nation's well-being,^[48] neighborhood renewal and regeneration.^[49] It has been assumed that they possess a sufficiently detailed "knowledge of, or interest in, the cultural needs of communities,"^[50] that this is central to their missions, and that they are "key to achieving the Government's overall goals of a safe, just and tolerant society and providing the opportunity for everyone to realize their true potential."^[51]

But, the rejection of instrumentalist arguments to justify support for cultural provision is becoming more vociferous. Twenty years ago, the publication of Myerscough's *The Economic Importance of the Arts in Britain* (1988) prompted economists to observe that the primary function of the arts was not to create economic impact.^[52] More recently a number of commentators have similarly disputed the political expectations of culture to solve social problems:

We assume, ludicrously, that the effect is embedded in the cultural form itself, released when it is 'consumed'. If this were true, then it would be relatively easy to give each of us doses of good culture, making us into model citizens. Few carry faith in cultural effect that far. Yet the popular accounts of the Mozart effect implied just that—a dose of a sonata would improve brain wiring and math ability.^[53]

The notion that culture can make the world a better place is arguably no more than a form of political displacement activity:

If we want to improve our children, our schools, our inner cities, and the lives of the marginal, the elderly, the impoverished, then we should do so directly, rather than argue for an injection of 'more arts.'

In some cases, improvements to such social and economic agendas could be addressed that more efficiently elsewhere. Measuring culture in relation to these and other political ambitions has come to be regarded by many

practitioners as “naïve”^[54] “extraneous” and potentially “antithetical to their basic functions and purposes,”^[55] and DCMS’s ambitions fundamentally appear to deny the “inherent value” of culture.

For its part, DCMS is discernibly moving away from its earlier commitment to the instrumentality of cultural provision. Conceivably prompted by the work of the think tank, Demos, which has sought to revitalize the importance of cultural value,^[56,57] Labour’s successive Secretaries of State for Culture, Media and Sport have not only indicated that their thinking has moved on, but have expressed doubts about the adequacy of attempts to measure their impact. Smith’s successor, Tessa Jowell, published a personal essay on *Culture and the Value of Culture* in which she proposed that culture should be “faced on its own terms and with recognition of what it does”^[58] and that the debate should be shifted back to “cultural value.”

Her successor and Labour’s third Secretary of State for Culture, James Purnell, pursued a similar train of thought. While maintaining that targets were probably necessary in 1997, he considered that public subsidy of culture needed less defense now than it once did. “We no longer need to quote export figures to get a hearing.” But despite still believing that culture and the arts remain “the most effective ways of reaching disaffected teenagers, of helping people to think about mental health, of regenerating inner cities or coastal towns,” he insisted that they would still matter

... even if they did none of those things. They are intrinsically valuable before they are instrumentally so. The arts hold the ring for our national conversation. They are where we find our meanings, individually and collectively.^[59]

He maintained that although encouraging attendance by priority groups was still vital, DCMS’s focus should shift to “... what people have access to. If any part of our cultural sector is substandard, doesn’t take risks, doesn’t push barriers, ducks difficult questions, it’s not worth subsidising. Garbage in, garbage out.”^[60] Indeed, he commissioned a review of the role that government and public funding can play in enabling excellence, “how we can move from top-down targets, to empowering and risk-taking.”

But even as the substance of the impact assessment of cultural institutions is changing, it is still assumed that the “inherent value of culture” is synonymous with its “transformative power” and that can raise levels of aspiration. For the Arts Council’s outgoing Chief Executive, this realization potentially shifted the focus of impact studies. He called “investigation into the value of culture itself in terms of its inherent power to move people, change people, and give people new meaning in their lives.”

... the issue is for researchers to try and understand better how that transformative value might be captured. This

raises some challenging questions: First, how can we begin to describe transformative experience? ... Second, can we find out what conditions need to be in place for transformative experience to happen? ... ‘What research techniques would be most applicable to an investigation of this nature?’^[61]

CONCLUSION

This entry has explored the introduction of the impact assessment of cultural institutions by the New Labour government which came to power in the 1997 general election. It has considered the rationale of the Department for Culture in doing so, as well as setting out the pragmatic and philosophical difficulties encountered. In tracking the development of impact assessment, particularly as it pertains to the English museums sector, this entry has demonstrated how the government’s attitude to the impact assessment of cultural institutions has shifted away from instrumentalism to cultural value. However, assessing impact still remains central.

Incunabula [ELIS Classic]

John P. Immroth

University of Pittsburgh, Pittsburgh, Pennsylvania, U.S.A.

International College of St. Bonaventure, Rome, Italy

Abstract

The word “incunabula” derives from the Latin word meaning “cradle.” Incunabula are books from the “cradle” of modern printing, that is, those printed with movable metal type in the fifty years from the invention of movable type to January 1, 1501. These books are the focus of special interest in the study of the history of books, and are designated with this special term. The development of printing during those years, and the search for, discovery, and analysis of books printed during that period are discussed in this entry.

—*ELIS Classic*, from 1974

INTRODUCTION

Incunabula are any books printed with movable metal type prior to January 1, 1501. This definition includes only the first 50 years of typographic printing. Block books or xylographic books of the same time period are normally not considered to be incunabula because they would not have been printed typographically (i.e., with movable metal type). It may also be noted that the exactness of the date of January 1, 1501, precludes many similar but later works. Most scholars today, however, accept this date as appropriate. Edwin Emerson states,

In correct English usage, the word “incunabula,” in my opinion, should be strictly limited to printed texts or titles or printers’ marks from the middle of the fifteenth century to its end. While previous blockbooks, printed from fullpage woodcuts with text, or the later products of some of the first printing presses of the early sixteenth century in England, Spain, Portugal, Mexico and Scandinavia are undoubtedly as rare and primitive as those of preceding printers in Germany, Bohemia, Switzerland, Italy, France and the Netherlands, so that the former books fitly could be said to be in their infancy or cradle, nevertheless neither they nor still earlier Chinese, Korean and Japanese prints from movable types or full page blocks are rated by competent scholars as incunabula. After all, even the most comprehensive students and insatiable collectors of early prints must draw the line somewhere in their ever extending researches. So they might as well draw the incunabula line between the Spring of 1450 and the last day of the year 1500.^[1]

Alfred Pollard defines this term in the eleventh edition of the *Encyclopedia Britannica*,

... a Latin neuter-plural meaning “swaddling-clothes,” a “cradle,” “Birthplace,” and so the beginning of anything,

now curiously specialized to denote books printed in the 15th century. Its use in this sense may have originated with the title of the first separately published list of 15th-century books. Cornelius Beugheem’s *Incunabula typographiae* (Amsterdam, 1688). The word is generally recognized all over Europe and has produced vernacular forms such as the French *incunables*, German *Inkunabeln* (*Wiegendrucke*), Italian *incunaboli* though the anglicized *incunables* is not yet fully accepted. If its original meaning had been regarded the application of the word would have been confined to books printed before a much earlier date, such as 1475, or to the first few printed in any country or town. By the end of the 15th century book-production in the great centres of the trade such as Venice, Lyons, Paris and Cologne, had already lost much of its primitive character, and in many countries there is no natural halting-place between 1490 and 1520 or later. The attractions of a round date have prevailed, however, over these considerations, and the year 1500 is taken as a halting-place, or more often a terminus, in all the chief works devoted to the registration and description of early printed books.^[2]

The extension of this date beyond the end of 1500 is found in Svend Dahl’s *History of the Book*. He states about his native area, “In the Scandinavian countries, when printing did not begin until the 1480’s the incunabulum period is extended to 1550.”^[3] Occasionally and inaccurately, the term incunabula may be applied to the first 50 or so years of printing in a country (i.e., American incunabula for early printed books in the United States). Konrad Haebler, a famous German scholar of incunabula, presents the following argument for justifying the January 1, 1501, date.

To-day, the end of the year 1500 is quite generally accepted as the close of the incunabula period. It agrees with the usage prevailing from early times to the present,

and is easily justifiable as an average date. The year 1500 is a very fitting limit for the early printing of Germany in particular, and as the home of the invention of the “black art” this country may well lay claim to special consideration. The mechanical side of the printing process had begun to gain footing in some places in Germany even before the year 1500. The prominent workshops in which that was the case, those of Anton Koberger in Nuremberg, Johann Grüninger in Strassburg, Peter Drach in Speyer, nevertheless had so undeniably gotten their start in the incunabula period, and so, not with standing their attention to the commercial aspect, still retained so much feeling for the scholarly and artistic conception of printing that it would be wrong to deny their books the characteristics of true incunabula. In any case, most of the smaller printing-shops which appeared in Germany up to the year 1500 bore quite unmistakable marks of the incunabula period. As far as Germany is concerned, we might feel in favor of extending the limit of this period still further, to the Reformation, for that was the first event to mark a general and obvious change in the field of printing. To do this, however, would be unfortunate, for the years 1501–17 in Germany were a time in which printing played a considerably diminished role as much in comparison with the preceding as with the following period.

In Italy we find a somewhat different situation. Here one must make a distinction between the printing of Venice, which began as early as the seventies to assume the leading role in the printing art in general, and the workshops of the rest of Italy, for their existence developed under essentially different circumstances. The incunabula period, as we have herein characterized its essentials, ended in Venice about 1480, for not in vain was Venice in the second half of the fifteenth century the indisputable centre of European commerce. . . . In the other Italian states conditions were almost the same as in Germany. . . . In fact, the introduction of italic by Aldus Manutius in the year 1501 plainly strengthens our conception of the end of the incunabula period as the year 1500.

In France, too, a distinction should be made between the printing of Paris and that of other cities. The limit for Paris was a considerably later one, however, than for Venice; yet about the middle of the nineties bookmaking even in Paris saw the introduction of methods of management which were contrary to the fundamental principles of their incunabula period. . . .

The situation was similar in other countries into which printing found its way before the end of the fifteenth century. Up to that time, however, Spain and England entirely lacked a centre in which, as had happened for example in Venice or Paris, the art should have had a chance to develop earlier than was possible in the provinces. Not with standing all their presses, in comparison to Italy and France, they remained provincial, their entire output persistently retaining the characteristics of incunabula even down to the sixteenth century. In the north and east we find printing only sporadic, often as offshoots of the workshops which we have already met with in the

older centres of culture. For all these countries, then, the limit of the year 1500 is altogether too early; yet this is not very significant, relatively speaking, since the entire book production in these regions in comparison with that of Germany, Italy or France is of no great importance. For all the reasons here set forth, then, the year 1500 is almost universally recognized as the limit of the incunabula period.^[4]

Attempting to make no such defense as Haebler does, the *Encyclopedia Britannica* simply states, “The limit is convenient but arbitrary, since no special development in the printing art can be connected with it.”^[5]

The first established use of this Latin word in relation to printing occurs in a tract, *De ortu et progressu artis typographicae* written by Bernard von Mallinckrodt, dean of Münster Cathedral, and published in 1639 in Cologne. This work was issued as part of the second centenary celebration of Gutenberg’s invention of typography. Mallinckrodt described the period from mid-fifteenth century to 1500 as “prima typographiae incunabula.”^[6] The first bibliographic use of this newly indicated time period was 4 years later in 1643 by J. Saubertus in *Historia bibliothecae reipublicae Noribergensis. . . Accessit. . . appendix de inventore typographiae itemque catalogus librorum proximis ab inventione annis usque ad a. Chr. 1500 editorium*.^[4] In 1653, Philippe Labbé equated the word with the time period in his *Nova bibliotheca mss. librorum s. specimen antiquarum lectionum latinarum et graecarum*.^[4] According to Haebler

The first independent catalogue of incunabula was that by Cornelis à Beughem, *Incunabula typographiae s. catalogus librorum scriptorumque proximis ab inventione typographiae annis ad annum Christi MD inclusive in quavis lingua editorum*, Amstelodami 1688, 8°. This was no longer the inventory of a single collection but a first attempt to comprehend the collected literature of the period of early printing, the author having brought together approximately three thousand titles.^[4]

Additional major incunabula catalogs and bibliographies will be covered in the following sections of this entry.

As the term *incunabula* became more commonly used to designate a particular period of typographic production, various vernacular forms developed. In English, the following three terms have all been used as a vernacular equivalent: incunables, fifteeners, and cradle-books; of these, incunables is the most common English term today. Three terms have also developed in French: *incunable*, *impression ancienne*, and *impression primitive*. *Incunable* is the most commonly used term of these three. In German, four terms have evolved: *Inkunabel*, *Wiegendruck*, *Frühdruk*, and *Erstlingsdruck*. Of these four terms, *Wiegendruck* is the most common. In Dutch, there are two terms: *incunabel* and *weigedruk*. The Spanish term is *incunable*. *Incunabulo* is the Italian term. The Russian is

ИНКУНАБУЛ (*inkunabul*). There are two terms used by the Scandinavian languages (Swedish, Danish, and Norwegian): *inkunabel* and *paleotyp*. In Finnish, there are three terms: *inkunaabeli*, *paleotyyppi*, and *kehtopaino*. The Polish term is *inkunabul*. The Greek is *τυπομαρχατοογ* (*typoma archaion*). The Bulgarian term is ИНКПУНАБУЛ (*inkunabul*). The student of incunable bibliographic literature should be aware of all these different terms that may be used to refer to *incunabula*. The catalogs of foreign collections will often have titles in the vernacular, although the entities will usually be listed in the original languages.

CHIEF REFERENCE WORKS

Possibly no other period in the history of printing has been so well covered (i.e., studied and described) by that which so nearly approaches a complete bibliography, as the period of the incunabula. As early as the end of the eighteenth century ("early" understood with reference to Sir Walter Greg's dating for the beginning of true bibliographical scholarship), George W.F. Panzer published at Nuremberg, during the period 1793–1803, an 11-volume study titled *Annales typographici ab artis inventae origine ad annum MD*. The first five volumes covered the history of typography from the invention of printing to 1500; in 1803, the study was carried on to 1536 and six more volumes were added. This work is considered by some scholars the first important modern bibliography.

Inspired by Maittaire's work, *Annales typographici ab artis inventae origine ad annum MDCLXIV* (Hagae-Comitum, 1719–1725), Panzer borrowed both Maittaire's title and basic method and set out to trace the course of early printing. In the *Annales typographici*, Panzer's principle of division is alphabetical. Listing the main printing centers alphabetically by their Latin names, he then arranged in seniority all the printers who worked in these centers and followed this by a chronological listing of their publications.

The *Annales typographici* is divided into two parts: the first lists books printed up to and including 1500, whereas the second part covers the years 1501–1535. Panzer's annalistic approach gives the *Annales* a rather pronounced scientific tone. And the entries (although brief) include a detailed reference to sources and are more complete and technical than those of his predecessor, Maittaire. Furthermore, by a careful examination of types, Panzer was successful, especially when studying the Strassburg printers, in assigning certain books, published without a printer's name, to a definite printer of that city.

Panzer's work was criticized by Proctor, who in his preface to the *Index to the Early Printed Books in the British Museum*, wrote that:

Panzer's method of grouping of books by years rather than printers has many merits, but obscures the work of the

individual printers, and is unsuitable to a work in which the chief stress is laid in this point, and on the types which the printers used.^[7]

Despite its limitations, Panzer's work is an early example of how the scientific method can add much to the knowledge of a printed book.

Twenty-three years after Panzer's *Annales*, Ludwig Hain published the *Reptorium bibliographicum in quo libri omnes ab arte typographica inventa usque ad annum MD. typis expressi ordine alphabetico vel simpliciter enumerantur vel adcuratius, recensentur* (Stuttgart, 1826–1838, 2 vols. in 4 parts). This is still considered the standard reference work for incunabula studies; but as Roy Stokes has rightly noted, in view of Greg's accomplishments, standard does not necessarily imply the note of immutability. It may nevertheless be considered and used as the first bibliographical tool and as a springboard to other studies in this period of printing history.

The *Repertorium* lists alphabetically and numbers consecutively (by author order) 16,000 books printed before the end of the fifteenth century. Because of Hain's death, the later part of the alphabet is incomplete.

Although the entries preceded by an asterisk were compiled by Hain himself from copies under his care at the Hof und Staatsbibliothek (Munich) and are, therefore, more detailed and descriptive, the others, relying on earlier (XVI, XVII) and contemporary bibliographers, are less descriptive and informative. Each entry is composed of an assigned heading and transcripts. The assigned heading includes the author's name and a brief title. The transcripts are of the incipit, major section titles, and colophon. A folio number is given with reference to the place of the incipit, explicit, and colophon in the incunabula. Thus, for example, in entry 13387, *F l a* plus the title caption means that this is to be found on recto of the first folio. When, however, the title caption is printed on a subsequent leaf, the form *F l a vacat* is used and the transcript made with the appropriate folio reference. (Cf., e.g., Hain 13463.) The explicit transcript (or colophon) is always preceded by the words *In fine* and is made in full in the style of the type used in the original text. (Cf., e.g., Hain 13408.) The collation of the incunabula is given in code (i.e., in a series of initials and abbreviations that need some practice to decipher). Thus, the collation for Hain 5530 reads: s. 1. a. et typ. n. f. g. ch. s.s. c. et pp. n. 2. col. 421. 304ff. This reads (when deciphered): sine loco, anno et typographici nomine, folio, gothicis characteribus, sine, signatoribus, custrodibus et paginarum numeris, 2 columnae, 42lineae, 304 folia. And when translated means: without place, year and printer's name, in folio, in gothic characters, without signatures, catchwords and page numbers, 2 columns, 42 lines to the page, 304 folios. It should be noted, as a point of useful information to students, that a list of the abbreviations used by Hain can

be found in Stillwell's *Incunabula and Americana 1450–1800*, pp. 223–225.

Hain's *Repertorium* is, as has been stated, important on account of the wealth of description that it affords the consultor. Although earlier bibliographers furnished the reader with a title for the incunabula based on the incunabula's contents, Hain faithfully recorded the incipit and explicit of each book. This exactness made it possible, for the first time, to identify books with a good amount of certitude and to check them for their completeness.

The *Repertorium* does fall short of the mark, however, on two counts: first, Hain's failure to furnish information that would help to link the books described with their printer; second, his failure to collate the signatures (when present).

To the *Repertorium*, there have been added a series of supplements, which have both augmented and corrected with the original material furnished by Hain. One of the most important of these supplements is the work prepared by W.A. Copinger and titled *Supplement to Hain's Repertorium Bibliographicum*. This work, published between 1895 and 1902, is—as scholars know, and students soon discover—far less accurate than Hain's and should be used with the greatest caution.

Copinger's *Supplement* comprises two volumes, divided into three parts. Volume I, Part I, lists 7000 corrections of collations and additions to collations of works already described or mentioned in Hain. This volume and part was severely criticized because of its many errors and because of the absence of certain authorities (whose presence, as quoted, cited, and referred to, scholars felt to be indispensable). The entries in Volume I, Part I, retain Hain's original numbering and are referred to as H–C (=Hain as corrected or added to by Copinger). Thus, for example, H–C 12259 is the same number in Hain as augmented/corrected by Copinger.

Volume I, Part II, furnishes the user with a list of numerous collations and bibliographical particulars concerning nearly 6000 volumes printed in the fifteenth century and not referred to by Hain. Here Copinger seems to have profited from previous criticism, for the level of his work is considerably better and he is careful to refer to authorities. The entries for this section are in Hain's style, but their numbering is Copinger's own, and an entry in this section is referred to as *Copinger*, *Cop*, or just *C* (always, of course, followed by the corresponding number). Copinger gives the collation before the transcript of the incipit and explicit (colophon). Although in Hain, undated editions are merely listed prior to the dated editions, Copinger instead based his order for undated editions by studying the number of lines per page. It was his contention that a smaller number of lines and a larger number of leaves probably indicated an earlier edition, and so he used this as his criterion for dating undated editions. He also retained (in Volume I, Part II) some of Hain's abbreviations and introduced the *sine notâ*

(without place, name of printer, or date) to be used if these were lacking.

Volume I, Part II, covers the alphabet from letter A to O, and Volume II completes the list of works not mentioned in Hain, covering letters from P to Z. It then furnishes an Addenda to Parts I and II.

Immediately after the Addenda to Part II, there was published as an index to Copinger's *Supplement*, Konrad Burger's *The Printers and Publishers of the XVth Century With a List of Their Works*. Some scholars think that the inclusion of Burger's study (which they consider to be the best brief chronological record of the output of each fifteenth century press) helped somewhat to redeem Copinger's work and give it a certain, acceptable status.

Burger's masterful work was, as he himself notes in the preface, a labor of love to which he could attend only after the day's work was over. What Burger did was to extract all the printers mentioned in Hain and list them (by their self-adopted names) in alphabetical order. Under each printer he then placed the dated books (in chronological order) and then (in alphabetical order) those issued *s. a.* and *s. n.* In his entries, usually kept to a single line to afford easy reference, Burger includes not only the books listed by Hain and Copinger but also adds material from Proctor, Pellechet, and Haebler. Burger also appended to his list a second listing of books which, although dated, bear no indication of printer or place of printing. Relying on Proctor's dating, he assigned to these impressions an approximate date.

Finally Burger, writing in the *Preface* to his *Printers and Publishers of the XVth Century*, apologized for not enumerating about 2000 books, which had appeared without indication of printer's name, place, and date. He also regretted not furnishing his readers with a listing of printing centers and indications concerning their printers and publishers. But he suggested that:

Whoever desires to gather information on this point may use Proctor's *Index*, which I recommend as a standard work for those engaged in the study of incunabula, and as a book from which further researches must start.^[8,9]

In 1905 D. Reichling published the first of six fascicles titled *Appendices ad Hain-Copingeri Repertorium Bibliographicum* (Munich 1905–1911, with a Supplement added in 1914). This work, which is much more authoritative than Copinger's *Supplement to Hain's Repertorium Bibliographicum*, is considered as a further step toward the goal of a complete bibliography of all fifteenth century books. Reichling furnished notices for more than 2000 incunabula not listed in Hain or Copinger and augmented/corrected about 3400 of their descriptions.

The *Appendices* is, as stated, published in six fascicles (fascicles I–VI, followed by an *Indices fasciculorum* numbered as I.VI, and then closing with a *Supplementum*) with two sequences running through them, all of which does not make this work very easy to use.

The first sequence, numbered consecutively, consists of books unknown to Hain and Copinger. This section is titled: *I. Additiones. Incunabula typographica Hainio–Copingero ignota*. The second sequence, consisting of additions, corrections, and emendations to entries in Hain, Hain–Copinger, and Copinger is titled: *II. Emendationes. Incunabula Typographica ab Hainio–Copingero minus accurate recensita*. Each entry in this second sequence or section is preceded by the appropriate number reference to (sic.) H. = *Hain, Repertorium bibliographicum*. H.C. = *Hain, Repertorium, et Copinger, Supplement P.I.: Corrections*. And Cop. = *Copinger, Supplement P.II., et vol. I. et II.: Additions*. Thus, for example, in Fascicle I: pp. 1–81 are the *Additiones* and pp. 83–206, the *Emendationes*.

The index for this work is to be found in Fascicle I.VI (*Indices Fasciculorum I.VI*) and is quite comprehensive. But in the *Supplementum* there is (besides additional entries) a General Index, which brings together in one alphabetical listing all the items listed in the preceding fascicle.

Again, it is suggested that before a student begins consulting Reichling, he page through the fascicles and become thoroughly familiar with the general layout and arrangement of the material. The *Appendices* may not be a very easy bibliographical tool with which to work, but it is nevertheless a very important one.

Influenced by the insights and contributions of previous and contemporary scholars, but most especially Henry Bradshaw, Robert Proctor (as V. Scholderer has remarked) found the history of early printing guesswork and left it a science.^[10]

Proctor's aim was to illustrate the history of early printing by listing (as far as possible) in chronological order all the fifteenth century presses and types. When he came to publish *An Index to the Early Printed Books in the British Museum: from the invention of printing to the year MD with notes on those in the Bodleian Library* (2 vols. K. Paul, 1898–1899; 4 Supplements 1899–1902), he had sorted out (on the basis of typographical evidence) and brought order to some 10,000 volumes, a third of which were, perhaps, without printer's names.

Basically, Proctor applied on a large scale Bradshaw's principle of natural history order. Going from the known to the unknown (as all science must), Proctor compared the types used in signed and dated books against those in books without date, name of printer, or even place of publication. He was so proficient at this identification that A.W. Pollard, writing in the *Introduction* to Volume I of the *British Museum Catalogue of Books Printed in the Fifteenth Century* (1908, p. xi) stated that Proctor could identify types almost always on sight. Pollard's remark is no exaggeration, for not only was Proctor able to identify the vast majority of the unsigned books that he studied, but subsequent studies have by and large attested to his accuracy. His work has, in fact, become the basis for the still

incomplete *British Museum Catalogue of Books Printed in the Fifteenth Century*.

Proctor's *Index* is arranged in what is now commonly known as Proctor Order. That is, the books are sorted out, on the basis of typographical evidence, under their countries, towns, presses, and dates.

Proctor intended that his *Index* should include all books printed up to 1520. He selected 1520 rather than the more commonly accepted date of 1500 because he felt that the initial period of printing really ended at this date.

The *Index* is divided into two parts. The first lists all fifteenth century books and concludes with an index listing places, printers, and publishers (all in alphabetical order). There are also—at the end of this first part—other indexes of authors arranged by their Hain or Campbell number and in alphabetical order. Part II lists books printed in Germany during the period 1501–1520. Proctor's death in 1903 left the *Index* unfinished. At his death he had completed only the first section of Part II (i.e., that covering Germany). It was left to Frank Isaac to complete sections 2 and 3 (covering Italy, Switzerland, and Eastern Europe). These were published in 1938.

Proctor's entries are brief: each book is given a short title and the general format is noted, but there are no further collational details. It must be remembered that Proctor's work was meant to be in fact, what it was in name, that is, *An Index*.

Some critics have objected that, properly speaking, Proctor's *Index* is more a catalog than a bibliography. The novelty and complexity of his approach was defended by Proctor himself in the Preface to his *Index*, when he stated:

They (the books) are arranged, mainly in chronological order, under the printers of them; the printers are arranged in their order under the towns, and the towns under the countries; the precedence assigned to countries, towns, and printers is the same in principle, and is determined by the *terminus a quo* in point of date, in each case.^[7]

When the first volume of the *British Museum Catalogue of Books Printed in the Fifteenth Century* appeared in 1908, Pollard set the question to rest when he noted in his Introduction that Proctor's experience with his *Index* had made this the obvious arrangement for a much more expanded catalog.^[11] Much of the importance of this superb bibliographical tool depends on its arrangement, which is in the Proctor Order.

It is good to remark here, as Roy Stokes has stressed all these years (in the classroom and in print), that although the student may make his first acquaintance with these bibliographical tools by general descriptions and introductions, he must do everything possible to enable himself to handle the books themselves. The student must become familiar with the scope and the arrangement of these bibliographical tools, for on his

knowledge and skillful use of them rests much of the efficiency that he is expected to exercise in the whole area of bibliographical scholarship.^[12]

EXTANT INCUNABULA

The normal reaction to the tremendous amount of work and superb scholarship that have been expended in the study and description of the incunabula is to wonder whether, indeed, there is anything left to uncover or discover, much less to describe. Pollard himself wondered if at times the game (in incunabula scholarship) was not played for its own sake without any great consideration of practical utility.^[2]

A solution to this questioning can be had by both remembering the past and keeping a keen eye on present developments in this area of historical bibliography.

Pollard believed that the total output of the fifteenth century presses is not likely to have exceeded 40,000 editions and that given the number of copies produced by an individual printer (250 copies by Roman printers, 300 by Venetian printers or even 500 copies toward the end of the century), a possible total of 20 million books were placed on the European market.^[13] Today, scholars believe they know about the existence of at least 48,000 incunabula (about three times the amount originally recorded by Hain). But these are neither all registered in a single listing, nor is their description always adequate or complete. Furthermore, it is not infrequent to come across the word/note “unrecorded” in sale catalogs.

Extreme caution must be exercised with regard to new discoveries and the word “unrecorded” in sale catalogs. In this matter, one need only recall the latest hoax uncovered by the Italian bibliographer Roberto Ridolfi, which was fully described and explained in his article, “‘Un incunabulo sconosciuto’ (e inesistente)” in *La Bibliofilia*, Firenze, 1971, pp. 191–195.

All this does not mean that there is absolutely nothing else to be discovered/uncovered. Rather it means that new discoveries will be difficult if not improbable. History, of course, will be the final judge, and the margin of possibility together with scholarly scepticism will always serve to make the future interesting.

An area of work does exist, however, in searching out libraries and private collections, and in aiming toward both a more accurate/exact description and a cumulative bibliography of all incunabula.

TYPOGRAPHICAL DETECTIVES

The study of typography, with the intention of using the types as bibliographical evidence for dating books is, certainly, one of the more scientific branches of bibliography.

Typography is not unlike paleography because the early types were imitations of the book hand.

Most of the fifteenth century printers both designed and cast their own types. Therefore, books not bearing a printer’s name can be assigned to a printer through the comparison and identification of the fonts. This theory is called the “one type, one printer” theory. Because a printer could (and, in fact, did) sell his fonts to others or even pass down his type to successors; many thought that the one type, one printer theory was no longer valid.

But the work of Bradshaw, Proctor, and Haebler (which to a large extent supported this theory) has in no way suffered from these doubts. In fact, their method has been vindicated by subsequent studies and scholars. Today all agree and know that types can be the most reliable guide to both determining a printer and dating a volume.

Henry Bradshaw, whom Greg has called “the founder, or one of the founders, of the modern study of typography, . . .”^[14] developed for the study of incunabula a theory based on Darwinism, which he called the natural history method. By grouping books together by origin, he was able to compare them and draw conclusions concerning their genus (i.e., press on which they were printed). His natural history method was worked out in *A Classified Index of the Fifteenth Century Books in the De Meyer Collection* and can be found in *The Collected Papers of Henry Bradshaw*, University Press, Cambridge, 1889, pp. 208–236.

Robert Proctor, who based his work on that of Henry Bradshaw, Holtrop and Campbell, was the first to study the identification of early types in great detail. The result of his labor, *An Index to the Early Printed Books in the British Museum: from the invention of printing to the year 1500 with notes on those in the Bodleian Library*, gave the world of incunabula scholarship the first clear picture of the development of fifteenth century printing and presses.

Useful and important as is Proctor’s *Index*, however, the best and to date most important handbook for typographical detection is Konrad Haebler’s *Typenrepertorium der Wiegendrucke*. The user will soon come to know—and so should be previously warned—that Haebler’s book is a difficult, but important, bibliographical tool. The *Typenrepertorium* is, in fact, a highly detailed classification of types based on the characteristics of design and (in part) of sizes. Haebler selected 102 forms of the upper case M (for Gothic types) and Qu (distinguishing between those printed as two letters or as a logo type) for Roman types. These two letters were selected because it was these that underwent the greatest amount of changes and variations.

The *Typenrepertorium* is divided into two parts: the first on the types of Germany and those countries, which were directly influenced by German printers, and the second covering the types of Italy, France, Portugal, England, and the Netherlands. Under each country, Haebler listed the towns alphabetically and then their printers in chronological order.

The types used by each printer are provided by a series of symbols and numbers. But most important for a fruitful use of Haebler's work is a frequent consultation and familiarity with the two indexes he provides—one for Gothic and a second for Roman type.

Haebler's work, of course, is not the final word, nor does it provide easy solutions to typographical detection. When the user can come to the conclusion that a type compares as closely as possible with what he finds in Haebler, then the next step is to check further in facsimiles, etc. But, as Roy Stokes has rightly remarked, great discretion is needed, and hasty identification is a snare, particularly after 1480.

EXAMPLES OF FAMOUS INCUNABLES

Of the approximately 40,000 editions printed during the incunable period, there are a few that are truly outstanding. These include examples of very fine printing as well as various notable first occurrences. The following discussion includes only a small number of these famous incunables.

Perhaps the most famous incunable is the so-called "Gutenberg Bible." Although there is no absolute proof that Johann Gutenberg of Mainz printed or rather supervised the printing of this Bible, he is generally given credit for planning and at least supervising the early stages of its printing. The completion of the work is assumed to have been done by Gutenberg's successors, Johann Fust and Peter Schoeffer in approximately 1455. A copy that was housed in the Mazarine Library in Paris is signed and dated August 15, 1456, by its rubricator and binder, Heinrich Cremer. The final version of the Bible was in two columns of 42 lines each; hence, this Bible is often called the 42-line Bible. It is the first printed book extant. Margaret B. Stillwell states, "There is a grandeur about this Bible, a superb air of finality, that stands in curious contrast to the fact that it is the first book to have been printed with movable metal types, and thus the starting point in the history of modern book-making."^[15] Of the estimated 150 copies on paper and 30 on vellum, there are 21 surviving, 3 of which are on vellum. A large paper copy was placed on sale for \$2,500,000 by Kraus.^[16] One of the vellum copies is on permanent exhibition at the U.S. Library of Congress. The type design in the 42-line Bible is *textura* or *Lettre de Forme*. *Textura* is the most formal of the types of the Gothic family and is sometimes called "Wedding text" or "Old English" by printers today.

The *Mainz Psalter* is the first printed book to have a complete colophon. It was issued by Gutenberg's successors, Fust and Schoeffer. It is a Latin Psalter dated 1457. The catalog of the famous Printing and the Mind of Man exhibition of 1963 describes it.

This famous masterpiece of printing surpasses even the 42-line Bible in the beauty of its type and the richness of

its ornament. It is the first printed book to give the name of its printer and the date of printing. One of the printers, Johann Fust, had been in partnership with Gutenberg and had advanced money for the first essays in printing. It is supposed that a lawsuit between the partners in 1455 led to the dissolution of the partnership and that thereafter Fust exploited Gutenberg's invention with the help of his son-in-law, Peter Schoeffer, the other printer named in this book.

The colophon at the end may be translated from the Latin as follows:

"The present volume of the psalms, adorned with beautiful initial letters and with the proper rubrics in red, has been given this form artificially by means of a contrivance for printing and inscribing without any use of a pen, and laboriously brought to completion for the service of God by Johann Fust, citizen of Mainz, and Peter Schoeffer of Gernsheim in the year of our Lord 1457 on the Eve of the Assumption" (i.e., on 14 August).

It is an extremely elaborate book, set in two founts of type, excellently cut and cast, with 292 impressions of initial letters cut in metal and printed in colours. The text was printed in black and red and the big initials in red and blue or grey and printed for the most part at one pull, but here and there by two impressions and some stamping by hand. The inking was remarkably laborious: the red and blue letters were picked out of the forme before each impression and separately inked; in the case of the two-colour initials, the block for background ornament, given its colouring, and put back (probably fastened in also) before each copy was printed. Many changes were made in the formes during the run, so that no two of the surviving ten copies, all on vellum, are alike.

Some authorities contend that Gutenberg had a hand in the early stages of the printing; but this can be no more than conjecture.^[17]

The type design is *textura*. Another edition was printed in 1459 by Fust and Schoeffer.

A third important book printed in Mainz is the 1460 *Catholicon*. It is a thirteenth century Latin dictionary compiled by Johannes Balbus and printed in Mainz in 1460. It is thought that Gutenberg may have been the printer. Binns says, "There is no definite evidence that he was, in fact, its printer, but most experts are agreed in crediting the work to him in default of any other person to whom it can be assigned."^[18] It is "the first printed publication of any work in the field of secular knowledge."^[16] A less formal Gothic type called *Fere-Humanistica* or *Lettre de Somme* is first used in this book.

Another important Latin Bible is the 48-line Bible printed by Fust and Schoeffer in Mainz in 1462. This is the first printed Bible to contain a colophon and the first printed appearance of the twin shields printer's device of Fust and Schoeffer. The Gothic type used is called

Fust–Schoeffer Bible type and has the overall appearance of Fere–Humanistica.

The *Subiaco Lactantius* is the first dated book to be printed in Italy. Two German printers from Mainz, Conrad Sweynheym and Arnold Pannartz, settled for a short time in Subiaco, Italy, and printed this book in 1465. The text is *De Divinis Institutionibus* or simply *Opera* of Lucius Coelius Firmianus Lactantius. The type is a semi-Roman or transitional face. It is also the first printed book to contain short passages of Greek type.

The Recuyell of the Histories of Troy, written by Raoul Le Fevre and translated by William Caxton, is the first book printed in English. Although the book is not dated, Binns says "...it is generally agreed that it was printed at Bruges between 1472 and 1475."^[18] In his epilogue Caxton states,

I have practysed & lerned at my grete charge and dispense to ordeyne this said book in prynte after the maner & forme as ye may here see, and is not wreton with penne and ynke as other bokes ben, to thende that every man may have them attones, ffor all the bookes of this storye named the recule of the historyes of Troyes thus enpryntid as ye here see were begonne in oon day, and also fynysshid in oon day.^[16]

This type face is of the Gothic family of a French Bastarda or Lettre Bâtarde. An edition of the French original, *Le Recueil des Histoires de Troyes*, appeared in 1476 and may have been printed also by Caxton. It is probably the earliest French literary work in print (see also *Caxton, William*).

Nicholas Jenson's first important book is probably Eusebius' *De evangelica praeparatione* printed in Venice in 1470. The type designed for this work is of the Roman family and called Venetian. It is considered to be one of the most beautiful Roman text types. B.A. Uhlenborn states, "...Jenson created the most beautiful Roman type we have: a perfect symmetry in size and form, an unparalleled imitation of the lapidary forms of Roman inscriptions, meeting at the same time all the requirements of a printing type."^[19]

A very famous book from Nuremberg was printed by Anton Koberger in 1493. Although commonly called the Nuremberg Chronicle, its correct title is *Das Buch der Chroniken* or *Liber Chronicarum* by Hartman Schedel and Georg Alt. It is a massive folio volume of 596 pages containing some 1809 illustrations from woodcuts by Michael Wohlgemuth and Wilhelm Pleydenwurff. Only 645 different wood blocks were used to make the many illustrations so that many illustrations are used more than once.

The *Hypnerotomachia Poliphili*, printed by Aldus Manutius in Venice in 1499, is often considered one of the true masterpieces of the incunable period. The Roman type face is Old Face designed by Francesco da Bologna.

The book is illustrated by delicate woodcuts and intricate initials. William M. Ivins analyzes this book in the following quotation.

It would be possible to name but few objects that have had the influence on subsequent design that this book had. In Venice and Italy it had little popular acclaim, its text too erudite and its illustrations too familiar in type and style, to arouse much interest. It took forty-odd years to sell off its first edition of six hundred copies, and with the possible exception of the *Nuremberg Chronicle*, which was too big to be read or used, it is today the commonest of fifteenth-century books. In the year of its second edition, 1546, a translation of it into French, accompanied by French copies of the woodcuts of the original, was published at Paris. This translation went through four or five editions, the last of which found a market after the beginning of the seventeenth century. It is doubtful whether any one set of designs has ever played so extraordinary a role as did this in the conversion of France from its Gothic to its Renaissance. It was the first and the greatest of the printed carriers of the revived classical feeling to the peoples of the north.

The *Hypnerotomachia* thus immediately raises several questions that are of extreme importance in any critical discussion of book design and illustration. As far as its text went it was an impossible, erudite, silly romance, fittingly written in a jargon that is almost macaronic, devoted in largest measure to abstruse symbolism and the maundering of a mad collector of classical remains. It describes, as only an Italian platonic humanist could, temples, groves, palaces, ruins, gods and goddesses, and fragments of ancient art. ... And it was illustrated with pictures of many of these things. Thus it happened that within the covers of this crazy book were to be found more representations, clear, lucid, and simple, of the architectural and monumental forms that intelligent Italy had evolved from the classical, than had ever before been printed. ... A richly illustrated book, filled with outline drawings of architectural motifs and details, vases, capitals, arches, pilasters, and other such things, it could not well escape being itself a rather effective object. ... Its draftsman was anything but a great artist, but its subject matter and the traditional technique in which he worked lent themselves most admirably to the creation of a homogeneous object of art. Between its letter press and its illustration there was no conflict or color or linear form—a result purely accidental, possible only because the draftsman lacked personality and his subject forbade it. Its success from the typographic point of view is grounded in the fact that its figures display almost as little personality or color or draftsmanship as those in a Euclid. The result is that by many in these modern times it has been declared to be the most beautiful of all illustrated books.^[20]

CONCLUSION

Many outstanding collections of incunabula exist in European libraries. The four most important collections, perhaps, are in the British Museum, the Bibliothèque Nationale in

Paris, the Staatsbibliothek in Munich (formerly the Royal Library), and the Vatican Library. In addition, there are major collections in the libraries of Berlin, Milan, Vienna, Manchester (including the John Rylands Library), Brussels, and The Hague. There are also many smaller European collections.

Although none of the American collections can truly match these European ones, the following libraries are noteworthy in this country: the Library of Congress, the Lenox collections of the New York Public Library, Harvard University Library, the Pierpont Morgan Library in New York, the Henry E. Huntington Library in San Marino, California, the Hispanic Society of America in New York, Columbia University Library, Yale University Library, Cornell University Library, the University of Michigan Library, the Chapin Library at Williams College, both the Newberry Library and the John Crerar Library in Chicago, the University of Chicago Library, the Free Library of Philadelphia, the National Library of Medicine, the Boston Athenaeum, the Grolier Club Library of New York, the General Theological Seminary Library, the Annmary Brown Memorial at Brown University, and the Lilly Library at the University of Indiana.^[15]

Indexing: History and Theory

Bella Hass Weinberg

Division of Library and Information Science, St. John's University, Queens, New York,
New York, U.S.A.

Abstract

The history and theory of human textual indexing are surveyed. Basic terms are defined, the extent of the literature is discussed, and key concepts are explained, with an emphasis on thesaurus-based indexing. A section on the consistency of human indexing leads to a discussion of automatic indexing algorithms. An assessment of the future of human indexing concludes the entry. Pages from an early printed index and a manuscript index illustrate the structural elements of index entries as well as features of the format of early indexes that are still found in contemporary publications.

SCOPE AND ORGANIZATION OF THE ENTRY

The focus of this entry is on the history of indexing practices and the theory of indexing. The emphasis is on serial/database indexing, but implications are drawn for related techniques in back-of-the-book indexing, concordances, and various indexing-related activities. Other articles in this encyclopedia address a variety of related topics, such as subject headings, descriptive cataloging, metadata, thesauri, and citation indexing. Although Anderson believes that indexing and classification are the same thing,^[1] this entry treats index headings that are arranged alphabetically, while hierarchical display of content indicators is discussed in other articles.

This entry begins with definitions of basic terms, proceeds to vogue words, and then surveys the literature of indexing. A history of indexing is followed by sections on the theory of indexing and on the use of thesauri in the indexing process. A discussion of the consistency of indexing serves as a segue to the section on automatic indexing, a method of content analysis that is always consistent. The entry closes with a summary and a discussion of the future prospects of indexing.

THE TERMINOLOGY OF INDEXING

Definitions of Basic Terms

An *index* leads from a known order of symbols to an unknown order of information. An index is in a different order from the document or collection to which it provides access. The card catalog of a library is a type of index. The book collection of a library is generally classified by subject. If one knows the author or title of a book of interest, one may use one's knowledge of the alphabet to locate entries for the author or title of the book in the card catalog. The bibliographic record will provide the call

number of the book, which indicates its location within the classified collection.

The type of index most familiar to us is one in which the entries are arranged in alphabetical order, with *locators*, such as page references, pointing to a text that is arranged in a logical, hierarchical sequence. The most common example of this is a book index: The text is in an order established by the author, usually treating general topics before specific ones. The index arranges the terms representing specific topics alphabetically.

In discussing the history of the word *index*, Wellisch^[2] noted that the term was once used to refer to many types of information structures: abstracts, titles, etc. The word *index* is still encountered today as a heading for tables of contents, although these are far less sophisticated information structures than indexes. A table of contents lists the chapter titles and headings of a systematically organized work; such a list can be generated automatically. An index, in contrast, provides efficient access to the specific topics covered in a document. Compilation of an index requires far more cerebration than does preparing a table of contents.

Although the word *index* has acquired a specific meaning, a recent article on the history of indexes^[3] calls an ancient pictorial catalog—not arranged in a known order—the first index. Many finding aids on the web that are called *site indexes* are in fact *site maps*; the latter are the equivalents of tables of contents.

An index *entry* consists of three elements: a heading, a subheading, and a locator. Of these, the first and last are required, and a subheading is optional. An example of an index entry with all three elements is

Libraries
Georgia, 365

These structural elements are found in the earliest indexes. Index entries with Roman numerals as locators can be

(a)

Fig. 1 (a) Part of the first page of the index to *Liber Cronicarum*, an incunable. Copyright Plantin-Moretus Museum, Antwerp (R 38.4). The introductory note begins with the word *tabula* [= index]. The locators are folio numbers in Roman numerals. The initial A was decorated by hand (cf. Fig. 1c).

seen in Figure 1a–c. Indented subheadings are in Fig. 1b. These illustrations come from an *incunable*, a book issued during the infancy of printing from movable type—before the year 1500.^[4]

The sample entry above could occur in the index to a book or to a single volume of a journal. In an index to multiple volumes of a journal, a volume number would precede the page reference. In an index to *multiple journals*, the full bibliographic reference would serve as the locator:

Smith, John. Libraries in Georgia. *American Libraries* 14
 (1): 25–26, January 1999.

A wide variety of locator formats has been described by Weinberg.^[5] Fig. 2 illustrates the use of a homily number, rather than a page number, in a manuscript index.^[6] Section number is often the locator in legal texts, while chapter and verse numbers generally constitute the locator in indexes to the Bible. Browne advocates the use of section

and paragraph numbers as locators to increase the granularity of indexing.^[7]

Klement^[8] has introduced the term “open- vs. closed-system indexing” to explain the difference between the indexing of journals and books, respectively. A key difference lies in the nature of subheadings for the two formats. Subheadings in books are *coined modifications*,^[9] i.e., phrases formulated by the indexer, while those in journals or databases are standardized; the former are more specific. In a book index, for example, one might encounter the heading–subheading combination “caffeine: effect on sleep”; in a database index, the combination may read “caffeine—adverse effects.” The introductory sections of controlled vocabularies (such as *Medical Subject Headings*) usually list their standard subdivisions along with rules for assigning them.

Both book indexes and journal indexes include (or should include) cross-references, although the number of such references should be minimized to save the time

(b)

Fig. 1 (b) Part of a page with entries beginning with T from the index to *Liber Cronicarum*. Copyright Plantin-Moretus Museum, Antwerp (R 38.4). Indented subheadings are in the left-hand column.

of the user. The network of cross-references is called a *syndetic structure*, a term coined by Cutter in his guidelines for a dictionary catalog.^[10] A book index has an ad hoc syndetic structure—one created by the indexer to link the synonyms and related terms relevant to that book. The cross-references in journal/database indexes are generally drawn from a thesaurus with preestablished term relationships.

Wellisch^[11] has published a glossary of indexing terminology. Dictionaries of library and information science also include definitions of indexing terms.

Vogue Words

Perhaps because the compilation of an index seems as simple as the ABC, the field of indexing is subject to the general linguistic phenomenon of *vogue words*, fashionable words that may not last long in the active vocabulary of speakers. Examples of vogue words germane to the field of indexing follow.

The term *metadata*, once reserved for data about websites, has been applied retroactively to all cataloging and indexing data. A recent article on early encyclopedias and indexes calls them *knowledge management tools*.^[12] This is ironic because the focus of the field of knowledge management is on the *unrecorded* information stored in experts' brains, while indexing deals with recorded documents.

Indexing is a type of *content analysis*, now often termed *knowledge representation*. (Abstracting is another type of content analysis, often done by indexers.) Amateurs call the process of assigning index terms *keywording*, although the term *keyword* usually means *free-text term*, not subject to vocabulary control. The controlled vocabularies used in indexing are now frequently called *taxonomies* or *ontologies*. Not long ago, they were called *knowledge bases*.^[13]

It takes some effort to analyze the vogue words of indexing in order to determine whether they are renaming a familiar phenomenon or naming a new one.

Fig. 1 (c) Part of the last page of the index to *Liber Cronicarum*, from a second copy of the incunabulum held by the Plantin-Moretus Museum. Copyright Plantin-Moretus Museum, Antwerp (R 9.7). The different style of the rubrics, as compared with the decorated A in (a), proves that the large initials were drawn by hand. Note the final line, “Finit registrum”; the latter word is a synonym for *tabula*, used at the head of the index.

THE LITERATURE OF INDEXING

The vastness of the literature about indexing is evident from the two book-length bibliographies on this subject compiled by Wellisch.^[14] Supplements to these appeared in *The Indexer*, the primary journal of the field.^[15] Recent publications on indexing have occasionally been cited in the state-of-the-art reviews entitled “The year’s work in subject analysis” in *Library Resources & Technical Services*,^[16] the journal of the division of the American Library Association that is most concerned with cataloging. The journal *Knowledge Organization* (formerly *International Classification*) until 2008 had a current-awareness bibliography^[17] that included many items germane to the field of indexing. Current issues (2017) have a column entitled “Books Recently Published.” State-of-the-art reviews on subject analysis in general, or on special aspects of indexing, were published periodically in the *Annual Review of Information Science and Technology*, which ceased publication in 2011.^[18] Coe reviewed the literature on the usability of

book indexes.^[19] Bell published a bibliography on the indexing of biographies and fiction.^[20]

The subject of indexing is also covered by the major print indexes and databases in the field of library and information science. Reviews of books on indexing have been collected in an anthology by Weinberg.^[21]

Several editions of a standard for indexes were approved by the American National Standards Institute (ANSI).^[22] The most recent revision failed to achieve consensus among the Voting Representatives of the National Information Standards Organization (formerly ANSI Committee Z39); the draft standard was published as a technical report.^[23] There are British and international standards for indexing as well; the British adopted the 1996 international standard^[24] as their own. Related standards were surveyed by Shuter.^[25] A standard for indexes to e-books is under development.^[26] These standards cover the principles and the format of indexes; the *process* of indexing is detailed in book-length manuals.

DISCIPLINES RELATED TO INDEXING

The preceding section on the literature of indexing provides some clues as to the disciplines related to indexing. The primary one is information science, formerly called *documentation*, with an emphasis on the detailed analysis of information contained in documents. Indexing is often taught in schools of library and information science, but about 50% of book indexers lack a degree in library and information science, and many journal/database indexers are trained in-house.

Indexing is germane to every discipline. The National Library of Medicine has rigorous rules for indexing the

literature that it acquires.^[27] The policies of databases in other disciplines are often unpublished.

A discipline particularly concerned with indexing is genealogy, as the indexing of names is the primary focus of genealogists. Indexing manuals used to have their own rules for the formulation of name headings, but in recent years these manuals deferred to the rules of the library cataloging community published in *Anglo-American Cataloguing Rules*, 2nd ed. (AACR2), which as of June 5, 2007, is no longer updated.^[28] AACR2 has been replaced by RDA (*Resource Description and Access*). Appendix F of the 2014^[29] edition of RDA contains guidelines for names in some languages other than English. Spidal

discussed these cataloging codes as well as other sources of name headings.^[30]

The international journal *The Indexer* has since 2006 been publishing a series of “Centrepieces” focusing on rules for formulating headings for names in a variety of languages;^[31] these articles provide more detailed guidance than AACR2 or RDA on the entry element of names in languages other than English, such as La Fontaine, Da Vinci, and Van der Camp.

The expansion of the Internet has stimulated interest in the history of the book and the organization of information. Evidence for this statement is the large number of books and articles published since the year 2000 that deal with the history of books and the impact of printing. Scholars of intellectual history and the Renaissance often write about early indexes and the encyclopedists. The literature of indexing is thus widely scattered. In documenting the history of citation indexes, Weinberg^[32] observed that early Hebrew citation indexes were described in journals in the field of religion, not in the literature of information science.

Indexing is of interest not only to academic communities but also to individuals, both scholars and laypersons. Within the context of information science, Jones^[33] has written about personal information management, which includes indexing the documents that one decides to keep. “Professional organizers” provide advice on the organization of personal files, focusing on the creation of category structures in which to file personal papers. Weinberg^[34] has reviewed a great many manuals authored by professional organizers and found most of the indexing advice incorrect. Many of these manuals advise their readers to file personal papers under the *broadest* heading they can think of, while *specificity* is considered praiseworthy in the field of indexing. Golub^[35] cites studies of how people organize their machine-readable files, notably e-mail.

HISTORY OF INDEXING

An index is a form of auxiliary memory. Historian Daniel Boorstin^[36] observed that indexing begins when memory declines. If one has not memorized a text that one has read, an index helps one locate the passage(s) of interest quickly, obviating the need for a sequential search of the text. An index also serves those who have *not* read the text. The title pages of early printed books (in Hebrew as well as Latin) that contain indexes often mention their time-saving nature.

Our knowledge of the history of indexing is limited because so much of the evidence has been destroyed by the ravages of time, the burning of books, and the fragility of materials on which information has been recorded. This is especially true for Hebrew books, which were often subjected to censorship and burnings. Furthermore, as Beit-Arié pointed out,^[37] Hebrew books tended to be

copied for personal use, while Latin books were copied in institutional settings, notably monasteries. In comparing the state of early Hebrew citation indexes with manuscripts of the first Latin citation index, Weinberg^[38] commented on the beautiful calligraphy and ornamentation in the latter.

Kilgour^[39] described the underlining of keywords in red in hieroglyphics documents. This is analogous to the marking of *indexable matter* (terms to be indexed) on the page proofs of books. Berger^[40] detailed the history of alphabetical order, which is essential to many indexes. Witty^[41] published one of the first papers on the history of indexing, beginning from antiquity and proceeding to the Middle Ages. Witty emphasized the concept of the *known order* of index entries as a means of facilitating access to written records.

Wellisch^[42] dated the origins of indexing to a fourth-century Greek work entitled *Apothegmata*, a collection of sayings of the Church Fathers. Weinberg^[43] has demonstrated that most early indexes were in the domain of religion, which was considered the “queen of sciences” in the Middle Ages. Fig. 2, a page from a manuscript index to the homilies of Pope Gregory, illustrates this point. Painting-Stubbs wrote about the early English indexes (1576–1587) of Abraham Fleming, many of which provided access to religious books.^[44]

Richard and Mary Rouse^[45] have described the earliest Latin Biblical concordances (word indexes), which date back to the early thirteenth century. Sophisticated concordances contained the three elements of index entries: a word from the Bible (the heading), the phrase in which the word occurs (subheading), and the chapter number (locator). Weinberg^[46] has demonstrated that selected lists of words from the Hebrew Bible were compiled by the Masoretes at least three centuries earlier, while Busa^[47] theorized that concordances to the Bible probably existed in the seventh century.

Rouse^[48] stated that subject indexes were invented in France; some of those compiled in the thirteenth century have sophisticated features, such as networks of cross-references. Weinberg^[49] described medieval indexes and concordances compiled in France, analyzing their structure and format. Failing to cite Wellisch, Cevolini^[50] cites Rouse and other authors who believe that indexing began in the thirteenth century. Humphreys posited that the oldest index is the 3000-yr-old *I Ching*, as she translated its hexagram structure into that of an alphabetical index.^[51]

Among the features of medieval indexes that are emulated today is the *introductory note*, which explains the structure of locators or some other aspect of an index. Introductory notes are evident in Figs. 1a and 2. Early printed indexes emulated the format of manuscript indexes, as was noted by Wellisch.^[52] This can be seen in Fig. 1a and c, which contain images from two copies of an incunable (a book from the infancy of printing, i.e.,

fifteenth century) with initial letters calligraphed in different styles.

Thesauri are considered to be an invention of the middle of the twentieth century, but work on synonym control and lexicography dates back to the ancient period. Krovetz^[53] has demonstrated that hierarchical relationships are embedded in definitions, e.g., “a horse is a *mammal*.” Thus, the roots of broader-term relationships in thesauri are in early dictionaries. Hlava^[54] reviews the history of such relationships, i.e., taxonomy.

Multilingual thesauri are considered a modern phenomenon, but Wellisch^[55] has described medieval multilingual herbals, in which plant names were provided in several languages and scripts. Wellisch^[42] also described a graphic display of relationships among index entries in an incunabulum.

Vocabulary switching is viewed as a contemporary problem, but sophisticated work was done in the 1930s on the translation of the American Library Association's subject headings into Library of Congress subject headings.^[56]

Wellisch^[57] described and translated a sixteenth-century manual of indexing written by Conrad Gessner, the “Father of bibliography.” Gessner provided detailed instructions for the technique of indexing: one should write index entries on sheets of paper and then cut the entries apart in order to arrange them in the desired order. In the twenty-first century, this method may seem laughable, but it is not as obsolete as one may think. As president of the American Society of Indexers, I chaired the jury of the H. W. Wilson Award for Excellence in Indexing; the award-winning indexer used a technique similar to that of Gessner: typing entries on adding-machine tape and later cutting them apart and alphabetizing them!

The Society of Indexers (in England) recently reprinted an early twentieth-century manual of indexing, considered a classic.^[58] Wheatley's book devoted a lot of attention to the format of indexes, but he also articulated important principles of indexing that are still cited. His dictum “one index, indivisible” is often violated in contemporary works, resulting in confusion on the part of the user of books with multiple indexes, online catalogs with unclear search options (e.g., subject/keyword), or websites that lack a single search box and require the user to select a category.

In sum, content analysis is an ancient activity; sophisticated indexes were created in the medieval period; and work on vocabulary switching antedates online searching and the Internet era.

THEORY OF INDEXING

Indexing is not really a theory-based profession. John O'Connor's dictum, “Good indexing permits good

retrieval” (stated at a conference of the American Society for Information Science), crystallizes the essence of the field, emphasizing its practical purpose. Principles of indexing have been inferred from practice. Wellisch^[59] criticized the high percentage of articles about indexing that describe individual projects without reference to principles or the prior literature.

Jonker^[60] wrote a book of indexing theory that was cited in Borko's paper “Toward a theory of indexing.”^[61] Svenonius^[62] questioned the theoretical basis of indexing and suggested directions for research, while noting the methodological difficulties of comparing indexing systems with different structures. Quinn^[63] reviewed more recent theoretical approaches, focusing on the subjectivity of indexing and on attempts to delineate the steps in the indexing process. Quinn also noted the lack of American theoretical contributions to the literature of indexing and classification.

The textbook of indexing authored by Lancaster^[64] records important principles, such as specificity, and demonstrates that all so-called theories of indexing in fact are not. He devoted particular attention to the “axioms” of Robert Fugmann. And yet, Hjørland has classified theories of indexing, including his own.^[65]

A key concept in the indexing literature is *aboutness*. Weinberg^[66] has suggested that the linguistic concepts of *topic* and *comment* should be applied to enhance the quality of indexes. This would, for example, facilitate the retrieval of documents containing negative views of a topic while excluding those with positive views. Andersen and Christensen^[67] also took a linguistic approach to indexing theory, suggesting that it be based on a philosophy of language, with particular attention to the theory of meaning. The authors applied the ideas of Ludwig Wittgenstein to indexing by stating that this process must take into account the social, historical, and linguistic contexts of documents.

While there is no generally accepted theory of indexing, there are standard measures of the characteristics of indexes. *Exhaustivity* of indexing is measured by the number of terms assigned to a document, such as a journal article, or by the number of index entries assigned to a page in a book. Weinberg^[68] discussed the exhaustivity of indexes in books, journals, and full text. She has attempted to get the indexing community to use the terms *entry* and *heading* consistently because the definition of entry has implications for the fee structure of indexers.^[69,70] Weinberg's letters to *Key Words* contain numerous references to publications on the density of indexing and related terminology. For example, the following line of an index with a heading and multiple locators represents four entries, although some indexers charge by the number of *lines* in an index:

Libraries, 40, 86, 112, 256

Density and *depth* of indexing are often-used synonyms for exhaustivity, although Wellisch^[71] defined depth of indexing as a combination of exhaustivity and specificity. Anderson^[72] has explained *specificity* as “goodness of fit”; in other words, a term in isolation cannot be called specific; its specificity can be evaluated only with reference to the text being indexed. For example, the term *Birds* is a specific descriptor for an article about birds in general, but it is not specific for an article about robins.

Ranganathan^[73] developed the concept of *coextensiveness* of classification numbers and index terms, i.e., that the full scope of a document should be expressed in a single classification number or index term. For example, if a document deals with the topic “The manufacture of silk shirts in 20th-century Italy,” Ranganathan believed that all facets of the topic should be represented in one classification number, synthesized from the elements that designate the key concepts. Alternatively, a single indexing string should contain all the concepts in a specified order.

The use of machines in the indexing process led to the concepts of *precoordination* (combination of terms at the indexing stage) and *postcoordination* (combination of terms at the searching stage). An example of a precoordinated index entry is the heading–subheading combination “Boston—Museums.” In a postcoordinate system, the two terms would be indexed separately and combined only at the searching stage. Kilgour^[74] wrote that the latter system began to replace precoordinated subject indexing in the mid-1930s. Taube^[75] worked extensively in the 1950s and 1960s on the development of [post]coordinate indexing.

Although postcoordination has been presented as superior to precoordinate indexing, the disadvantages of the former method of indexing have been pointed out by several experts in the organization of information and summarized by Weinberg.^[76] Milstead^[77] noted that it is not a question of better or worse: precoordination is the *only* appropriate method in the print environment. Human beings were not designed to compare lists of document numbers posted to keywords in order to locate a combination of concepts. In using printed indexes or card catalogs, humans require subheadings in order to quickly locate documents that deal with the aspect of interest.

Soon after the implementation of postcoordinate indexing, it was recognized that the loss of word order led to many *false drops*, i.e., the retrieval of documents that were not relevant to the query. If one were seeking information on the Philosophy of History, for example, one would retrieve documents on the History of Philosophy. To deal with this problem, information scientists developed the devices of *roles* and *links* to connect related descriptors. It was quickly recognized that these artificial devices were not assigned consistently, and they were abandoned. Weinberg^[78] has reviewed many complex indexing systems that were dropped, including those based

on contemporary linguistic theories. Craven^[79] described numerous *string indexing* systems—systems in which a set of terms is selected by a human indexer but manipulated by computer.

In library and information science, there has long been a distinction between technical services and public services. But just as reference librarians must understand the structure of a catalog, so must online search intermediaries understand how databases are indexed. Kesselman and Perry^[80] have discussed this, with particular reference to the way precoordinated or multiword terms are processed by online vendors. Searching is the obverse of indexing. As searching of the World Wide Web by end users has increased, consultation of fee-based databases has declined.

Frohmann^[81] criticized those who wrote about the mental process of indexing. Anderson responded to the criticisms in his textbook.^[82] Bates^[83] reviewed research findings on indexing that are germane in the Internet era. She focused on the mismatch between the terms used by the indexer and the searcher, the inconsistency of naming concepts and objects, and on folk classification. The last-mentioned topic is currently receiving a lot of attention in the context of social networks and tagging by laypersons.

Indexing is an art, not a science. Many intelligent people lack the ability to distill the essence of a document and to represent its main topics in a few words. Some people who have gone through formal training will never make good indexers, while others who are self-taught are excellent indexers and have even won awards in the field.

An indexer must be something of a prophet—envisioning the concepts likely to be sought by users of a document, expressing those concepts in terms likely to be sought by users, and providing cross-references from synonyms and alternative spellings as well as links to related terms to assist users in finding all the information that is relevant to their topics of interest.

THE USE OF THESAURI IN INDEXING

This section explains how the features of thesauri are used in the indexing process. The most common term for a preferred heading in a thesaurus, i.e., a term that may be assigned in indexing, is *descriptor*. Numerous synonyms exist for descriptor, including *postable term*, i.e., a term on which index entries may be “posted.”

An indexer scans a document and thinks of terms that represent its “aboutness.” If the term selected by the indexer is a synonym of the preferred term in the thesaurus, there will (or should) be a USE reference from the nonpreferred term to the descriptor, e.g., “attorneys USE lawyers.” If the term selected by the indexer is more specific than any of the descriptors, the thesaurus may provide a USE reference from a *quasi-synonym* (not a true synonym), e.g., “chairs USE furniture.” The reciprocal of USE

is UF (Used For). By examining the terms coded UF, the indexer sees which terms are considered equivalent:

lawyers
UF attorneys
barristers

The rationale for the USE/UF relationship is that the time of the user will be saved if information is not scattered among synonymous or nearly synonymous headings. The equivalent of USE in book indexes is the command *see*.

A descriptor may be followed by a scope note (SN) that tells the indexer when to assign the term; SNs often refer to related headings. An example of an SN that does this is taken from the Educational Resources Information Center (ERIC) Thesaurus.^[84]

Occupational Home Economics

SN formal preparation for occupations using home economics knowledge and skills—below the baccalaureate level. (Note: For the baccalaureate level and above, use “Home Economics Education.”)

A study conducted in Israel found that for nearly a third of the index terms assigned to books by librarians using a Hebrew thesaurus, there was no information relating to those terms in the books.^[85] This was explained by the lack, or inadequacy, of SNs in the thesaurus used for indexing.

A thesaurus record for a descriptor often displays narrower terms, coded NT. If an indexer has selected too general a term, the NTs lead the indexer to the most specific term available:

plants
NT flowers

flowers
NT roses

Reference librarians are well aware that users express their information needs in more general terms than they actually require; such librarians are trained to draw out the true information need via a reference interview. When users consult indexes on their own, the downward cross-references serve this function. In a book index, *see also* is the (rough) equivalent of NT.

The reciprocal of NT is BT, for *broader term*. BTs set the hierarchical context of a descriptor:

flowers
BT plants

Some indexing systems have the practice of *upposting*, i.e., assigning a more general term in addition to the

descriptor that matches the scope of the document. In older subject heading lists and in book indexes, *see also* references to BTs are usually not provided, although some argue that such cross-references would be especially useful to children, who may have a hard time thinking of BTs if they find little information on a specific topic of interest. For example, if the subject of interest is Turtles, and all the books on that subject have been borrowed from the library, a child may not think to look under the broader term Reptiles.

The final code for semantic relationships in standard thesaurus format is RT, for *related term*. RTs are descriptors that are neither broader nor narrower than the selected term, but semantically related to it. Usually, RT relationships in thesauri are symmetrical: Gold RT Money; Money RT Gold. In older subject heading lists and in book indexes, RT is represented as *see also* in both directions. In light of recent studies of user persistence, showing that laypersons input one or two words to a search box and do not try synonyms or related terms if the search fails, RT references are essential to help users modify or expand their searches.

USE references are called *prescriptive*; they give an instruction to the indexer: You may not use this term; you must use the preferred term. BTs, NTs, and RTs are *suggestive* references; they ask the indexer to consider other terms that may be more appropriate for the document in hand.

James Anderson believes that indexers should not be constrained by controlled vocabularies. (He has expressed this opinion at conferences of the American Society for Information Science.) Anderson recommends that indexers assign the terms they feel are appropriate, and that *post-control* be done by a thesaurus editor: identifying synonyms and related terms, and coding them appropriately.

In indexing operations that use thesauri, indexers are (or should be) encouraged to propose new terms and semantic relationships through paper or electronic forms. The speed with which new terms are added to an indexing thesaurus affects users' perceptions of the quality of an index. Obsolete descriptors make a poor impression.

Some indexing operations use a combination of descriptors and *identifiers*. ERIC has descriptors for topical terms, and *identifiers* for proper names and newly minted terms. ERIC has been controlling (i.e., standardizing) its proper name identifiers, just as libraries establish name headings in authority files. Topical identifiers in ERIC, such as *burnout*, may later be upgraded to descriptors.

Some indexing systems have a combination of descriptors and *free terms*; the latter are uncontrolled terms made up by the indexer, usually for highly specific topics not represented in the thesaurus. Keywords made up by authors may also complement the descriptors assigned by indexers, as is mentioned in Wikipedia's article on “Subject indexing.”^[86]

A wide variety of thesaurus display formats and codes exist. These are explained in the NISO thesaurus standard.^[87] Translating one structure into another requires considerable training. Indexers as well as searchers—not to mention end users—may not comprehend the structure of complex thesauri, and this may affect the quality of indexing and retrieval.

Most members of indexing societies work on books, creating ad hoc syndetic structures, as was noted earlier. Workshops and tutorials about thesauri are increasingly being offered to such indexers.^[88] Thesauri may be constructed to enhance searching, i.e., they operate behind the scenes to add synonyms and, perhaps, related terms, to the search terms input by an end user. Studies of this practice have been reviewed by Shiri.^[89] Errors in, and omissions from, Shiri's references to thesaurus standards are in a review of his book.^[90] Hlava^[91] describes more recent standards for thesauri.

One of the rationales for indexing with a thesaurus is that this enhances consistency. Indexing consistency is considered a measure of indexing quality; this is discussed in the following section.

CONSISTENCY OF INDEXING

The fact that there are no rigorous theories or rules for indexing is reflected in the repeated finding that human indexing is highly inconsistent. A thorough review of the literature on indexing consistency published through 1975 was done by Leonard.^[92] Saracevic,^[93] who conducted an important study of the consistency of *searching*, cited more recent studies of indexing consistency and observed that in all phenomena related to words, consistency rarely exceeds 25%. This has become evident in the Internet environment, with social tagging, i.e., the assignment of "keywords" by laypersons, as is noted by Golub.^[94]

It is to be expected that terms assigned to electronic documents and images by those not trained in indexing will be highly inconsistent, but a low percentage of inter-indexer consistency is obtained even among professionals using a controlled vocabulary.

As Lancaster pointed out, there is no single correct set of index terms for a document.^[95] Indexing may be slanted to the purpose of an organization, in which case it is called *mission-oriented* indexing. Stibic's book on personal documentation for professionals^[96] takes this idea to the level of an individual. Index terms assigned by individuals may have nothing to do with "aboutness."

INDEXING THEORY AND AUTOMATIC INDEXING

One of the arguments for automatic indexing is that it is always perfectly consistent. In order to develop an

algorithm for automatic indexing, one must have a theory of human indexing. Most of the early algorithms for automatic indexing were statistically based: they theorized either that the most frequent words—excluding function words (e.g., *the*, *for*)—in a text are the content indicators, that the rarest words in a collection are significant, or that terms that are relatively more frequent in a single document than in a collection are significant. In research done for her dissertation, Weinberg^[97] tested all these theories and found that none of them yields results that match those of human indexing.

Another approach to automatic indexing is *positional*. It is based on the assumption that words in certain fields, such as titles and figure legends, are significant. Human indexers also look closely at such components of a document to select index terms. In fact, an international standard^[98] suggests doing precisely this.

Most automatic indexing is *extractive* (or *derivative*) indexing—pulling out terms from a recorded text, while human indexing entails *assignment* indexing—assigning terms from a controlled vocabulary, or composing index headings and subheadings without reference to a standardized list. Terms assigned by humans may not occur in the text at all, or they may appear as morphological variants of the standardized term, e.g., *registration* (a noun) for *register* (a verb in the text).

The main reason that automatic indexing algorithms fail to do a thorough job of content analysis is that a substantial percentage of humanly assigned index terms are not expressed in the text. Human beings are good at identifying concepts that are not explicitly named in a text; computers perform poorly in this regard.

Machine-aided indexing projects include those that have a computer select terms from a text and then consult a machine-readable thesaurus. If a synonym of the selected text term is the preferred term in the thesaurus, the computer assigns the latter to the document. An early system of this kind was implemented at the American Petroleum Institute;^[99] that system still serves as the basis of Machine Aided Indexer, a software package of Data Harmony. Hlava's *Taxobook* includes a screenshot of this software in which a pop-up window displays suggested terms for assignment to a text.^[100]

At information science conferences, the concern has been expressed that when computers suggest terms to indexers, these people will view the machines as oracles and will accept the suggestions without evaluation of their validity and without thinking of errors of omission.

Most of the early experiments on automatic indexing were done on journal articles. For a short while, a product was available whose developers claimed could index books automatically. Two prominent indexers tested the product and wrote such a critical review of it in 1994^[101] that the software was withdrawn from the market. Fifteen years later, a software package called TExtract received mixed reviews.^[102]

Book indexers use specialized software to assist them with the clerical aspects of indexing, but term selection and entry formulation are done by human beings. As Hirschmann observed in 2011, “Although we currently have several tools that assist in the preparation of back-of-the-book indexes, their preparation by computers without human intervention seems to be beyond their reach, at least for now.”^[103]

SUMMARY

Indexing is an intellectual activity with a practical purpose—fast retrieval of information. This activity began in ancient times and was highly developed in the Middle Ages.

The selection of content indicators is not subject to rigorous rules, but a scholarly terminology has been developed to characterize various aspects of indexing, such as its depth, and whether the index terms are pre- or postcoordinate. Theories of the mental process of indexing have been subjected to sharp criticism. Indexing remains an art.

FUTURE PROSPECTS

In the late 1990s, I was asked by an editor of *The Indexer* to predict the future of indexing after the millennium. Many of the observations made in that article^[104] remain true 25 years later.

The paperless society has arrived far less quickly than predicted. Despite improvements in the format of e-books, traditional books continue to be printed, and the nonfiction ones (at least) require indexes.

Automatic indexing experiments on journal articles have not eliminated human indexers and thesaurus designers. In fact, indexers have found new markets in developing indexes for websites, as many users recognize the limitations of keyword retrieval. Browne and Jerney^[105] produced a manual of website indexing that covers both concepts and software.

Anderson^[72] expressed the view that only important documents merit human indexing; the rest should be indexed by machine. In the Middle Ages, texts in the domain of religion were considered important and thus received detailed indexes. Today, medical texts are more likely to get thorough indexes, compiled by a professional. When the managers of an organization realize the advantages of fast and thorough access to information, they will pay for the compilation of indexes to printed corporate documents as well as websites.

The Semantic Web is a nice vision, but far from being implemented. As Moore wrote, “The semantic web has so far failed to live up to the initial hype surrounding it at the turn of the millennium.”^[106] Many of the writers on the

Semantic Web seem to have no background in library–information science. Northedge demonstrated that the origins of *topic maps*, which are considered a Semantic Web technology, lie in indexing.^[107]

There must be substantial advances in computational linguistics and natural language processing before the need for human indexing is eliminated. Artandi^[108] made a similar observation more than four decades ago: “. . . additional research is needed, both in linguistics and in the theory of indexing, to develop methods which will compare favorably with good human indexing.”

The recent founding of indexing societies in countries including China, South Africa, Germany, and the Netherlands—as documented in *The Indexer*.^[109]—provides evidence for the viability of the profession of indexing and for international interest in the principles and best practices of providing efficient access to information.

ACKNOWLEDGMENTS

Much of the historical research reported in this entry was done with travel grants from the Eugene Garfield Foundation. I am grateful to all the libraries that graciously afforded me access to their rare indexes.

Abstract

The National Library, Kolkata, is the largest single library that serves as the depository as well as the repository of all the published material of India. It also has built up a large collection of foreign publications. Besides, there are two other national libraries, namely, National Science Library, New Delhi and National Medical Library, New Delhi. There are a large number of academic, research, public and special libraries. Steps are being undertaken to modernize the libraries to meet the increasing demands of users. The National Archives of India (NAI), New Delhi, is the premier records repository of India. It has set up four regional archival repositories in Bhopal, Bhubaneswar, Jaipur, and Pondicherry. Each State has its own archives. There are a large number of college and university archives, corporate archives, religious archives, manuscript repositories, etc. India is a country that is rich in culture, heritage, science, and artifacts. Its museums and art galleries house a great cultural heritage. The National Museum, New Delhi, is the apex museum in the country. In addition to State museums and art galleries, there are a large number of art museums and galleries (noncommercial) that display India's rich heritage. India is also rich in biodiversity. The National Zoological Park, Delhi, is one of the finest zoological parks in India. Some of the best jewels of Indian wilderness include the Great Himalayan National Park, Dachigam National Park, Corbett National Park, Ranthambore National Park, Sundarbans National Park, and Kaziranga National Park.

INTRODUCTION

With a rich cultural heritage, India has one of the oldest civilizations in the world. With a population of 1.14 billion, India is the world's largest democracy. It has made tremendous socioeconomic progress during the last 62 years since its independence (1947). Today, India has become the tenth most industrialized country in the world.

of the Executive branch of the Union is the President. But the real executive power lies with the Council of Ministers that has the Prime Minister as its head. There are 28 states and 7 Union territories in the country. In the states, the Governor, as the representative of the President, is the head of the Executive body. However, Union Territories are administered by the President through an Administrator appointed by him.

Geography and Population

India covers an area of 32,87,263 sq km. It is bounded by the Great Himalayas in the north, the Indian Ocean on the east, and the Arabian Sea on the west. The population of India was 1,028,737,436 based on the 2001 census, but the projected population as of March, 1, 2008 is 1,147,677,000 (592,245,000 males and 555,432,000 females).^[1]

Government

India, also known as Bharat, is a Union of States. It is a Sovereign Socialist Democratic Republic with a parliamentary system of government. The constitutional head

History

The History of India begins with the birth of the Indus Valley Civilization, more precisely referred to as the Harappan Civilization. It flourished around 2500 B.C. in the western part of South Asia (present Pakistan and Western India). By 1500 B.C., the Harappan Civilization came to an end.

In the third century B.C., King Ashoka united large parts of India. During the reign of the Mauryas (322–185 B.C.E.), Hinduism (the major religion of India today) as a religion took a form that basically exists even now. It was during the eighth century that Islam first came to India. However, by the eleventh century, it had established itself as a strong

political force. The North Indian dynasties of the Lodhis, Tughlaqs, and others ruled India and were succeeded by the Mughal Kings.

From the mid-eighteenth century to the mid nineteenth century, India was gradually annexed by the British East India Company. The dissatisfaction with the rule of the East India Company resulted in a revolt that assumed the form of the 1857 Mutiny. This led to the First War of Indian Independence (1857–1858). After this war, India was incorporated into the British Empire completely and began to be directly administered by the British. During the first half of the twentieth century, a nationwide struggle for independence from British rule was initiated by the Indian National Congress. It was a long struggle. In 1947, the subcontinent of India gained freedom from British rule and the subcontinent was partitioned into the countries of India and Pakistan.

Education

The national level pattern exists with 12 years of schooling (8 + 2 + 2), consisting of 8 years of elementary education (that is, 5 years of primary and 3 years of middle school education for the age groups of 6–11 and 11–14 years, respectively), followed by secondary and higher secondary education, of 2 years of each, besides 2 years of preprimary education. The entry age in class 1 is 5+. Preprimary classes form age group 3 to 4. The higher secondary school certificate enables students to pursue studies either in universities or in colleges for higher education in general academic streams and in technical and professional courses.

According to the recent report of the National Sample Survey Organisation (NSSO), in 2005–2006 the literacy rate was 68.3%.^[2] Thus, goal of universal elementary education and total eradication of illiteracy has not been achieved so far. To achieve the goal would require higher level of investment in school education, especially at the elementary level.

The higher secondary school certificate enables students to pursue studies either in universities or in colleges of higher education, in general academic streams and in technical and professional courses. Today, India has a well-developed system of higher education, especially in engineering, technology, and management science.

The Emerging New India

India's greatest asset is a large pool of talent with more than 620 million people of working age. A large majority of its population is young, ambitious and dynamic, and has great aspirations. Its economy is growing rapidly. John F. Welch, Chief Operating Officer of General Electric, said "India is a developing country, but it is a developed country as far as its intellectual infrastructure is concerned. We get the highest intellectual capital per dollar here."^[3]

Toward the end of twentieth century, R. Mashelkar in his presidential address to the Indian Science Congress, made a prediction that "The next century will belong to India, which will become a unique intellectual and economic power to reckon with, recapturing all its glory, which it had in the millennia gone by. . . ."^[4]

LIBRARY AND INFORMATION PROFESSIONS, SYSTEMS AND SERVICES

Library Legislation

Pre-independence period

The first landmark in the pre-independence history of the public library movement in India was the enactment of the Delivery and Registration of Publications Act of Bombay Government in May 1808. Almost a century later, on January 31 1902, the Imperial Library Act was passed, creating the Imperial Library at Calcutta (now called Kolkata). In the history of library legislation, passage of the Kolhapur Public Libraries Act, 1945, remains a landmark event. It was the first public libraries act to be enacted in pre-independent India. This Act is now defunct.

Post-independence period (1947–2000)

The Imperial Library (Change of Name) Act, 1948 (Act no. 51 of 1948) was enacted on September 8, 1948. Thereafter, the Imperial Library came to be known as "The National Library". The Delivery of Books "and Newspapers" (Public Libraries) Act, 1954 [The delivery of Books (Public Libraries) Act, 1954: No. 27 of 1954, as amended by the Delivery of Books (Public Libraries) Amendment Act, 1956: No. 99 of 1956.] is another important Act. This is an Act that provides for Delivery of Books to the National Library, Calcutta, and to three other public libraries (Delhi Public Library, Delhi; Connemara Public Library, Chennai; and State Central Library, Mumbai).

Indian Copyright Act, 1957 and as amended in 1994/1995 governs matters related to copyright, including computer software. The act, as amended in 1994/1995, has incorporated many provisions keeping in view the changes in information technology. The Information Technology Act, 2000 (No. 21 Of 2000) [June 9, 2000] deals with issues concerning transactions carried out by means of electronic data interchange and other means of electronic communication, that fall under "electronic commerce."

"Through the good offices of the then Minister for Education, Avinaslingam Chettiar, a modified Bill was introduced in the state legislature which was passed as the Madras Public Libraries Act in 1948."^[5] Thus, due to the efforts of Dr S. R. Ranganathan, Father of Library Science in India, the Madras (Tamil Nadu) Public

Libraries Act was enacted in 1948. This was the first public libraries act to be passed in independent India.

The following public libraries acts were passed:

1. Madras (Tamil Nadu) Public Libraries Act (1948)
2. Andhra Pradesh Public Libraries Act (1960)
3. Mysore (Karnataka) Public Libraries Act (1965)
4. Maharashtra Public Libraries (1967)
5. West Bengal Public Libraries Act (1979)
6. Manipur Public Libraries Act (1988)
7. Kerala Public Libraries Act (1989)
8. Haryana Public Libraries Act (1989)
9. Goa Public Libraries Act (1993)
10. Mizoram Public Libraries Act (1993)

Twenty-first century

The following public libraries acts were passed:

1. Gujarat Public Libraries Act (2002)
2. Orissa Public Libraries Act (2002)
3. Uttaranchal Public Libraries Act (2005)
4. Rajasthan Public Libraries Act (2006)
5. Uttar Pradesh Public Libraries Act (2006)

Thus, through 2008, out of 28 states and 7 Union territories in the country, only 15 states have enacted library laws.

National Library and Information Services

Introduction

There are three national libraries of India, namely, the National Library, Kolkata; the National Medical Library, New Delhi; and the National Science Library, New Delhi. Other important libraries include the Central Reference Library, Kolkata that compiles *Indian National Bibliography* and *Index Indiana*. As mentioned above, Delhi Public Library (DPL), Connemara Public Library, Chennai and the State Central Library, Mumbai, are the depositories for the printed cultural heritage of India under the Delivery of Books “and Newspapers” (Public Libraries) Act. These depository libraries are not the national libraries in the strict sense of the term but form a very important part of the National Library sector because India is a vast, multi-lingual country with a rich written heritage in different Indian languages, including English. Thus, the need to cover the large country is realized through a network of national libraries and depository libraries.

There are a number of national documentation centers in different fields. These include the National Institute of Science Communication and Information Resources (NISCAIR) (formerly called Indian National Scientific Documentation Centre), the National Social Science Documentation Centre (NASSDOC) and the Small Enterprises National Documentation Centre (SENDOC). In this list,

we may also include the Defence Science Information and Documentation Centre (DESIDOC). These documentation centers were set up mainly to serve the fields of science, social sciences, small-scale industries and defense science respectively.

National Information System for Science and Technology (NISSAT), New Delhi, was launched in September 1977 as a national level coordinating and funding agency for creating information infrastructure in the area of Science and Technology. This agency was set up and supported by the Department of Scientific and Industrial Research, Government of India. NISSAT created and supported over 13 sectoral information centers, in specific subjects, such as leather, drugs, machine tools, food, etc. By 2004, the NISSAT program ended but the host institutions are continuing the centers with their own resources.

The University Grants Commission (UGC) is the apex body that monitors and funds higher education in the country. It established three information centers covering different disciplines as given below:

- National Centre for Science Information (NCSI) at Indian Institute of Science, Bangalore,
- National Social Science Information Centre (NASSIC) at M.S. University, Baroda (now called Vadodara), and
- National Information Centre (NIC) at SNDT Women’s University, Mumbai.

NCSI covers science and engineering, while NASSIC and NIC deal with the social sciences (such as economics, political science, education, and psychology) and other disciplines (such as sociology, women’s studies, home science, special education and library science) respectively.

Role of Government of India in relation to libraries

Under the Government of India (Allocation of Business) Rules,

the work pertaining to the Central Libraries of national importance, the Delivery of Books Act and publication of rare manuscripts is assigned to the Department of Culture. The Central Government, is not a lawmaker for a library system of the country as a whole as the subject ‘Libraries’ is included in the State list. However, the Central Government takes initiative to secure the voluntary cooperation of the State Governments and to promote coordinated development of national, and State Library system... Apart from maintaining and developing the libraries of national importance, the Central Government is giving financial assistance to libraries sponsored by voluntary organizations throughout the country.^[6]

The National Library, Kolkata

The National Library, India is the largest library in the country (see Table 1), located at Kolkata (formerly

Table 1 National Library Statistics as of 31 March 2006.

Books	2,402,579
Books in Indian languages	6,006,508
Maps	88,047
Manuscripts	3227
Books received under the D.B. Act	1,009,182
Current periodical titles	17,530
Bound volumes of periodicals	139,961
Newspapers (titles)	905
Bound volumes of newspapers	11,745
Indian Official Documents	499,509
Microfilms	5553
Microfiche	96,997
Shelf space	More than 45 km
Area of Belvedere Campus	30 acres

Calcutta City). It is an institution of national importance under the "Department of Culture, Ministry of Tourism and Culture, Government of India." The major aim of the library is to collect, disseminate and preserve the printed material produced in the country. Another important aim of the National Library is to collect all the books published on India, in any part of the world, in any language. At the same time, it is also collecting foreign materials in different languages for the use of the country.

The National Library receives books and periodicals in almost all the Indian languages under the Delivery of Books and Newspapers (Public Libraries) Act 1954 (D.B. Act). It also has

an invaluable collection in English language, because of the systematic collection development by Calcutta Public Library as well as by the Imperial Library. Way back in 1848 itself, an attempt was being made to acquire journals issued by the foreign learned institutions. Serious works were purchased in large numbers than the light literature. Now a days also the same policy is being continued.

It has a strong collection in the humanities, British and Indian history and literature.^[8] Digitization of books is a useful project, undertaken by the Library. To date, 6600 selected books in Indian and English languages have been scanned and stored on 548 CDs, covering a total of over 2,500,000 pages.

The library has separate reading rooms in all of its four buildings, and for each language division, the Foreign Language Division, Foreign Official Documents, Rare Books, Maps and Prints, Science and Technology Division, and Asutosh Collection. Any person above 18 years can use the reading room facilities.

Limited number of books are lent out to the readers (local members) under certain terms and conditions. To use this facility, one has to become a member of the Lending Division of the library. Outstation persons (members living outside Kolkata) are allowed to borrow books through post.

Selected lists of reading materials or bibliographies are prepared by the library on request. Special bibliographies are also compiled when exhibitions are held. Compilation of exhaustive bibliographies is underway on special topics, such as Indology. The library is responsible for providing bibliographies and/or bibliographic statistics to national and international organizations.

Central Reference Library (CRL), Kolkata

The Central Reference Library is a subordinate office of the Ministry of Culture, Government of India. It was carved out of the National Library, for the compilation of the *Indian National Bibliography* and *Index Indiana* (an index to selected articles appearing in current language periodicals).

National Medical Library, New Delhi

The National Medical Library (NML) aims to provide wide and efficient library and information services to the health science (HS) professionals in India. The Library is mainly a reference library in the field of Medical and Allied Sciences. It is open for consultation by Medical, Paramedical and Allied Professionals. The National Medical Library is considered one of the largest medical libraries in South Asia. It has 360,000 volumes of books, reports, bound volumes of journals and other literature and adds about 3000 books and serials every year. It subscribes to 2000 current periodicals. NML is also the National Focal Point of HELLIS (Health Literature Library and Information Service) Network set up by WHO in Southeast Asia in 1982.^[9]

NML has established a network of health science libraries in India. For this purpose, it has identified six Regional Medical Libraries (RML) and eight Resource Medical Libraries (RL) in the country. All RMLs and RLs have been provided with equipment such as micro-computers, CD-ROM Drives, the MEDLINE database and a photocopier. A grant-in-aid has been provided to each RML and RL to strengthen their document collection.

National Science Library, New Delhi

The National Science Library (NSL) was set up in 1964 as a part of Insdoc (now named National Institute of Science Communication and Information Resources (NISCAIR)). NSL aims at acquiring all-important Science and Technology publications published in the country and strengthening its resource base for foreign periodicals by acquiring the journals on CD-ROM or other electronic form as far as possible. The library is open to the public. Individuals and institutions can become members to use its collection.

NSL has a collection of over 200,000 volumes including monographs and bound volumes of journals in the fields of science and technology. E-Resources include

CD-ROM databases of primary and secondary sources and E-Journals. NSL has an Electronic Library Division with a collection of more than 5000 foreign journals, conference proceedings, etc. and a large number of databases on CD-ROMs. Services include Readers' Service, Technical Query Service, Copying Service, Inter-Library Loan Service, e-Journals Access (The library provides free access to electronic journals from 13 leading international publishers).

The Indian Agricultural Research Institute Library, New Delhi

The Indian Agricultural Research Institute Library (IARI Library) is a focal point for collecting, organizing and disseminating agrobiological information generated within the country as well as abroad. Due to its rich collection and services, it may be regarded as a national library in the field of agriculture. However, it has not been formally designated as such.

IARI Library has the largest collection in the field of agriculture and is considered a primary library in this field in India. The Library has over 600,000 highly specialized research publications on agriculture and related sciences. The collection is growing annually at the rate of 8000 to 9000 documents. The Library has 10,500 serial files, and 4000 current serials are being procured from 80 countries through subscription, gifts and exchanges.^[10]

National Institute of Science Communication and Information Resources, New Delhi

The National Institute of Science Communication and Information Resources (NISCAIR) came into existence on September 30, 2002 through the merger of the National Institute of Science Communication (NISCOM) and the Indian National Scientific Documentation Centre (INSDOC) (Set up in 1952). Its mission is to become the

prime custodian of all information resources on current and traditional knowledge systems in science and technology in the country, and to promote communication in science to diverse constituents at all levels, using the most appropriate technologies.^[11]

NISCAIR is basically concerned with collection, storage, publication and dissemination of science and technology information. It is a premier institution of information science engaged in dissemination of information in the field of S&T.

National Social Science Documentation Centre, New Delhi

The Indian Council of Social Science Research (ICSSR) was set up in 1969 as an autonomous organization to

promote research in social sciences in the country. In 1970, ICSSR established the Social Science Documentation Centre that was renamed the National Social Science Documentation Centre (NASSDOC) in 1986. It has a rich collection of reference sources, bibliographies, 5000 doctoral theses, 3500 research project reports (funded by the ICSSR) and 12,500 books and documents. NASSDOC has created a number of databases and information locating tools.

Defence Scientific Information and Documentation Centre (DESIDOC), Delhi

DESIDOC functions as a central information resource for DRDO (Defense Research and Development Organization). It provides science and technology information, based on its library and other information resources, to the DRDO headquarters as well as its various laboratories located at various locations in India. DESIDOC maintains an excellent library in the defense sector. It has more than 262,000 documents and provides document supply to its users quite fast. The library management activities have been computerized. More than 1000 DRDO scientists (and a few others) are provided monthly SDI (Selective Dissemination of Information) services, based on about 10 CD-ROM databases. It also brings out a number of publications to serve its users.

Small Enterprises National Documentation Centre, Hyderabad

The Small Enterprises National Documentation Centre (SENDOC), Hyderabad, was set up in 1971 as an organ of the SIET Institute. This Institute is now called National Institute for Micro, Small and Medium Enterprises. The Centre serves as a national bibliographic center to meet the information needs of micro, small and medium enterprises.

Inter-library cooperation

Today, there are several library networks that have come into existence to advance inter-library cooperation. A number of library networks were originally sponsored by NISSAT (National Information System for Science and Technology), such as ADINET (Ahmedabad Libraries Network), BALINET (Bangalore Library Network), BONET (Bombay Libraries Network), CALIBNET (Calcutta Libraries Network), DELNET (Delhi Libraries Network, now Developing Library Network), MYLIBNET (Mysore Libraries Network) and PUNENET (Pune Libraries Network). MANLIBNET (Management Library Network) was formed by libraries in the field of management.

A number of consortia have been formed. These include Indian National Digital Library in Engineering Sciences and Technology (INDEST), Council of Scientific

and Industrial Research Consortium, UGC-INFONET (established by INFLIBNET Centre links more than 172 universities across the country) and ICICI Virtual Information Centre. One of the major activities of these consortia is resource sharing.

National planning

Planning at the national level is done through five-year plans. At present, XI Plan (2007–2012) is in operation. The following thrust has been identified by the Ministry of Culture as a major Thrust Area for the XI Plan (2007–2012):

Overhauling the library sector to meet the needs of a knowledge society has been found to be the need of the hour by the Ministry... The recommendations of the National Knowledge Commission will be taken into account while formulating the XI Plan proposals in the Library sector.^[12]

With the efforts that are going on, it is hoped that it will bring major changes in the library sector, including the national libraries.

Academic and Research Libraries

Size of the sector

As of March 31, 2006, 355 universities and 18,064 colleges existed in the Higher Education sector. During the academic year 2005–2006, the total enrolment in all courses and levels in regular stream had been 11,028,000 including 4,466,000 female students (40.5%). The strength of the teaching faculty in universities and colleges was 488,000. The number of research degrees (Ph.D.) awarded during 2004–2005 was 17,898.^[13] The above data shows that the higher education sector is a massive one.

Main players in the higher education sector

The University Grants Commission (UGC) is “responsible for coordination, determination and maintenance of standards, release of grants.” Professional Councils are “responsible for recognition of courses, promotion of professional institutions and providing grants to undergraduate programs and various awards.” Central Government is “responsible for major policy relating to higher education in the country. It provides grants to the UGC and establishes central universities in the country.” State Governments are “responsible for establishment of State Universities and colleges, and provide plan grants for their development and non-plan grants for their maintenance.”^[14]

Higher education—history

Problems of educational reforms were reviewed by several commissions and committees, notably the University Education Commission (1948–1949) and the Secondary Education Commission (1952–1953). Some steps to implement the recommendations of the Commissions were taken and a Resolution on Scientific Policy was passed under the leadership of Jawaharlal Nehru, the then Prime Minister of India. As a consequence of the resolution, development of science, technology and scientific research received special emphasis. The Education Commission (1964–1966) was appointed to advise the Government on the national pattern of education and other matters. Its recommendations on education are a landmark in the history of education in India. A new education policy (NPE) was adopted by the Parliament in 1986. A revised Programme of Action (POA) was placed in the Parliament on August 9, 1992, and approved by it. The eighth five-year plan (1992–1997) was prepared keeping in mind 1986 NPE and 1992 POA.

The National Knowledge Commission (NKC) is a high-level advisory body to the Prime Minister of India, formed with the objective of transforming India into a knowledge society. In 2007, it gave its recommendations for higher education.^[15] The recommendations of the NKC are far reaching in nature. For example, it recommended creation of 50 National Universities that can provide education of the highest standard. These can result in revolutionary changes leading to excellence in higher education.

College libraries

A college, in general, is an institution of higher learning that offers a three-year degree after higher secondary school. However, most professional degrees are of four-year duration. Some colleges offer postgraduate courses of two-year duration. Usually, research is the prerogative of universities rather than colleges.

Colleges in India are regarded as the forerunners of universities. The same is true for college and university libraries as well. Collections of college libraries usually consist of books and periodicals. They may have some nonbook materials. However, the situation is changing. College libraries are increasingly acquiring nonbook materials. Most of them do not provide open access. The majority of the libraries use the *Dewey Decimal Classification* system and *Anglo-American Cataloging Rules*. As regards services, they render lending service, help to users in the location of materials and the use of the library catalog, and provide library orientation to new members. Some college libraries also provide bibliographical services. Teachers are usually provided with intensive reference service and inter-library loan. As regards the

photocopying service, it is usually provided by a private vendor appointed by the authorities under the conditions laid out by the authorities. The vendor may set up his machine within the library or anywhere on the college campus.

In recent years, many college libraries have automated their operations. The University Grants Commission (UGC) provides one-time grants for computerization of college libraries. In Delhi, a large number of college libraries have been computerized. Recently, the University of Delhi provided 40 computers to each college library affiliated with it, along with network facility and access to databases available at Delhi University Library System. Thus, faculty and students of colleges have free access to the total resources of the Delhi University Library System. Some of the colleges are using IT to provide highly specialized services. For instance, Farook College, Kozhikode, has set up the Digital Talking Book Library for the benefit of visually challenged students and named it "Insight."^[16] College libraries in metropolitan towns are well developed. However, libraries in small towns in economically underdeveloped states are in a poor state of development. UGC has recognized some leading colleges as autonomous colleges that get special assistance from UGC. Libraries attached to autonomous colleges are especially well equipped and maintained.

University libraries

The University Grants Commission. The University Grants Commission (UGC) was set up by the Central Government in 1953. However, in November 1956 the UGC was formally established through an Act of Parliament as a statutory body of the Government of India for the coordination, determination and maintenance of standards of university education in India. The UGC is the only grant-making agency in the country that has been given two responsibilities, namely: 1) providing funds and 2) coordination, determination and maintenance of standards in institutions of higher education. It also advises the union and state governments on measures to be taken in higher education.

UGC formulates rules and regulations for overall teaching and research at higher education. It also looks after the academic libraries (sets various standards for library education, library staff, library services, etc.). Committees are set up by the UGC from time to time for the support of higher education in general and the library services in academic (university and college) libraries in particular.

The UGC Panel on Library and Information Science is a standing body that examines and makes recommendations about issues and library problems. In 1957 UGC appointed the Committee on University and College Libraries to advise it regarding functioning and management of libraries. UGC adopted many of the recommendations from the

report of that Committee as norms for college and university libraries.

Present Scenario. University libraries in India have developed steadily but have not succeeded fully in their objective to build up sound library collections as a base for providing satisfactory services. However, the scene is changing due to the application of information and communication technology (ICT).

The UGC meets most of the total expenses of central universities. However, in the cases of state universities and institutions deemed universities, UGC adds to their funds for various development activities under the five-year plans. Libraries attached to central universities receive large financial support compared with libraries of state universities. Very often, state university libraries all over the country are starved of funds.

Information and Library Network (INFLIBNET Centre), has been a boon to university libraries. It is an autonomous Inter-University Centre of the UGC. It has supported many university libraries for creating computer facilities, databases and automation of libraries. It has also given training on a large scale to library staff in computer application, thus preparing them for modernization of libraries and their operations. The UGC-Infonet Digital Library Consortium launched by INFLIBNET Centre provides current as well as archival access to

more than 4500 core and peer-reviewed journals and nine bibliographic databases from 23 publishers and aggregators in different disciplines. So far 120 Universities out of 171 that come under the purview of UGC, have been provided differential access to subscribed e-resources.^[17]

University libraries have participated very actively in information and library networks that have been set up in recent years and benefitted considerably from these networks.

The above mentioned consortium is a program wholly funded by the UGC and executed by the INFLIBNET (Information and Library Network) Centre, Ahmedabad. The benefit of subscription to e-resources will soon also be extended to colleges, to begin with the College for Potential with Excellence (CPE). The Consortium also "plans to launch its "Associate Membership Programme" wherein private universities and other research organizations, would be allowed to join the Consortium for selected e-resources."^[18]

Public Libraries

The nineteenth century

The enactment of Delivery and Registration of Publications Act of Bombay Government in May 1808 is considered as the first landmark in the pre-independence history

of public libraries in India. Calcutta Public Library was established in 1836. It was not a Government institution. It was being run on a proprietary basis. The Calcutta Public Library is regarded as the first public library in this region of the country. Khuda Bux Oriental Public Library, Patna, was established in 1875. In 1969, it was declared, an institution of national importance under an Act (the Khuda Bakhsh Oriental Public Library Act, 1969) of the Parliament. On March 22, 1890 the foundation stone of Connemara Public Library was laid at Madras (now Chennai) and on December 5th 1896, it was formally opened. It is today, an excellent library with a rich collection and is heavily used by the public.

The Imperial Library was formed in 1891 by combining a number of Secretariat libraries. The most important one was the Library of the Home Department. However, the use of the library was restricted to the senior officers of the Government.

By the middle of nineteenth century, the towns of Bombay, Calcutta and Madras had subscription libraries, established with the active support of Europeans. By the end of nineteenth century,

all the provincial capitals and many district towns had so-called public libraries. In addition many princely states had public libraries in their capitals (e.g., Indore, Travancore-Cochin, Patiala). However, in general the masses did not take full advantage of those institutions.^[19]

The beginnings of the “public library movement in India can be traced to 1885, when the Indian National Congress was founded. This was the time when national awakening was taking place, leading to cultural renaissance. The Swadeshi movement was taking root.”^[19] Towards the end of the century, political, economic, and social pre-conditions necessary for the origin of public libraries were coming into being due to the awakening of national pride in national culture and heritage. National leaders, such as Bipinchandra Pal and Lala Lajpat Rai were responsible for this awakening.

The twentieth century (up to 1947)

On January 31, 1902, the Imperial Library Act was passed. This is considered as another landmark in the pre-independence history of public libraries in India. The Imperial Library, then located at Metcalf Hall, Calcutta (now called Kolkata) was formally opened to the public on January 30, 1903. The aims and objectives of the Imperial Library, were defined in a Notification in the “Gazette of India.”

It is intended that it should be a library of reference, a working place for students and a repository of material for the future historians of India, in which, so far as possible, every work written about India, at any time, can be seen and read.^[20]

Maharaja Sayajirao III, Gaekwar of Baroda, an enlightened ruler, thought of establishing public libraries along modern lines throughout the State of Baroda. Therefore, he invited W.A. Borden, the Librarian of the Young Men’s Institute, New Haven, Connecticut, to fulfill his dream. During the period of Borden’s stay, 1910–1913, he established the Central Library and initiated a public library system. The modern public library movement in India began in Baroda during the first decade of the century, due to the efforts of Borden, who was fully supported by the enlightened Maharaja.

In the year 1914, a public Library was established in the Seshadri Iyer Memorial Hall at Cubbon Park, Bangalore. In 1966, this library was taken over by the Government of Karnataka and was given the status of the Central Library. However, in 1986, this library was redesignated as State Central Reference Library.

Post-independence period (twentieth century, from August 15, 1947 onward)

After independence, the Government of India changed the name of the Imperial Library to the National Library, through an enactment of the Imperial Library (change of name) Act, 1948. Delhi Public Library was started initially by Government of India in 1951, as a UNESCO project. The purpose of the Library was to serve as a model public library for Asia. It is claimed that today, Delhi Public Library is the biggest Public Library System in India and also one of the busiest Public Libraries in South East Asia.

Public library scene in the states

The public library scene is briefly described for five states that have developed, comparatively speaking, better public library systems. These are Andhra Pradesh, Karnataka, Kerala, Tamil Nadu, and West Bengal. In the state of Andhra Pradesh, there are nearly 5000 public libraries including 2348 village libraries.^[21] The Department of Public Libraries of Karnataka State has established a large network of public libraries consisting of 3778 libraries including 3251 Gram Panchayat (rural) Libraries. There are, in addition, 42 aided libraries.^[22] In Kerala State, the State Central Library is a separate independent Department, functioning in isolation. Kerala State Library Council looks after public libraries in the state. The Government releases grant-in-aid to 3458 public libraries of different categories through Kerala State Library Council. Library Service is provided to the public cent per cent in cities and towns and 90% in villages.^[21] The public libraries in Kerala are well developed. The coverage of rural population is of a very high order, compared with other states. The State of Tamil Nadu has set up a network of public libraries. The total number of public libraries is 3751 including 1492 village libraries. Besides this, there are three Government aided libraries.^[23] West Bengal is the only state in India having a separate Minister

in-charge of library services. It has 2465 public libraries including 2209 rural libraries.^[24] The state has a fairly well-developed public library system.

Raja Rammohun Roy Library Foundation, Kolkata

The Raja Rammohun Roy Library Foundation (RRRLF), established in 1972, is a central autonomous organization. It is the nodal agency of the Government of India for supporting public library services and systems as well as promoting the public library movement in the country. It also functions as an advisory and consultancy organization and a funding body for public library development in India. Since its inception, the Foundation has “assisted 31,274 libraries in the country under various schemes,” such as construction of library buildings, increasing book stock, centenary celebrations, preservation, TV-VCP, computer application in libraries, children section, mobile library services, public library research, etc.^[25]

The twenty-first century

Computer Applications. The public libraries are being modernized. Toward this aim, they are undergoing the process of computerization. Computerization of public libraries started in early 1990s. Initially, it was slow and now it has picked up. RRRLF has played a significant role in computerization of public libraries. It has provided computers to all state central libraries and district central libraries. For instance, Delhi Public Library started automation of library activities in the year 1995 by installing Computers.^[26] During the last decade of the twentieth century, computerization was started at Connemara Public Library. However, it was in 1998 that 2 servers and 12 nodes were added. The staff input 350,000 records.^[27] In June 2003, OPAC (Online Public Access Catalog) was introduced. A touch screen system for library information was also added. An Internet Browsing center, a separate CD Room Section and book bar code were introduced in 2005. Now renewal of books due can be done online. Computerization facility has been “extended to 17 District Central libraries in Tamil Nadu. . . The remaining 12 District Central Libraries will be provided with computers in 2004–2005.”^[28] The Directorate of Library Services, West Bengal, has created a database of the Public Libraries of West Bengal. All data regarding the Government Sponsored Public Libraries is available in the database.

Public Libraries Acts. In twenty-first century, five states have enacted public libraries acts. These are Gujarat Public Libraries Act (2002), Orissa Public Libraries Act (2002), Uttaranchal Public Libraries Act (2005), Rajasthan Public Libraries Act (2006), and Uttar Pradesh Public Libraries Act (2006). Thus, today out of 28 states and 7 Union territories in the country, only 15 states have enacted library law.

Table 2 Penetration of public libraries.

Category (number)	Library type (number)	Coverage
States and Union Territories (35)	State Central Libraries (28)	80.0%
Districts (592)	District Libraries (451)	76.0%
Talukas ^[a] (3987)	Taluka Libraries (501)	2.5%
Villages (587,226)	Rural Libraries (28,820)	4.9%

^aA taluka is an administrative division forming part of a district within a state or union territory.

Source: Cited in Das and Banwari.^[29]

Penetration of Public Libraries in India. From Table 2, we may conclude that urban areas are comparatively well covered by libraries but talukas (sub-areas below district level) and rural areas are almost totally neglected. This data is quite old. Today, there may be around 100,000 public libraries (an estimate). Now, there is a greater stress on development of public libraries in rural areas. In recent years, a number of schemes for public library development in talukas and villages have been introduced.

Rural Libraries. “Lack of resource is another serious bottleneck in developing library services. The condition of the majority of rural libraries, particularly, in the heartland of India, is extremely miserable.” The situation of majority of rural public libraries is indeed truly miserable. This is in spite of the efforts of a national agency like RRRLF and state governments. “On analysing the trend of assistance rendered by Raja Rammohun Roy Library Foundation in the course of 28 years, it is found that the lion’s share of assistance . . . in the current year goes for the rural people of our country.”^[21]

Till recently, public libraries in rural areas were neglected as an area for library growth and development. But now, these areas are getting special attention from the center and state governments. For instance, in Tamil Nadu, a District Rural Development Agency (DRDA) has been set up in each district. One of the DRDA’s aims is to establish rural libraries.

The School Education Minister of Tamil Nadu announced the State Government’s proposal “to set up about 12,400 rural libraries within the next five years under the scheme ‘Anaithu Grama Anna Marumalarchi Thittam’ to benefit the rural population.”^[30] Similar schemes are being implemented in rural areas of different states. Nongovernmental organizations, such as Rajiv Gandhi Foundation have been quite active in this regard.

Role of nongovernmental organizations

Maharashtra and West Bengal have a long tradition of voluntary organizations providing public library services. “From 1830s, 100s of voluntary organizations came up in

the States, more so during the freedom struggle this led to establishment of 1000 of subscription libraries which charged annual subscription and a deposit to finance the library.” The Manipur Government passed the library legislation in 1967 and declared subscription libraries as public libraries. The Government of West Bengal passed its library law in 1979 and covered most of the subscription libraries as sponsored libraries.^[21]

Nongovernmental organizations are becoming more active in recent years, aiming to empower women, rural areas and backward areas through public libraries. One such example is that of the Rajiv Gandhi Foundation (established in 1991). The Foundation has nurtured a countrywide village library program since 1993. “In all, since 1993, RGF has established a total of 1444 libraries in 22 states, which includes 1344 village and 100 slum libraries.”^[31]

National policy

In October 1985, the Government of India constituted a committee under the chairmanship of D.P. Chattopadhyaya to formulate the National Policy on Library and Information System (NAPLIS). The final report was submitted, via a letter of May 30, 1986. It is an excellent report. However, the national policy was never approved by the Parliament. Another report that deserves special mention was submitted by the National Knowledge Commission, appointed by the Government of India. In its report on libraries dated December 7, 2006, it recommended setting of a National Commission on Libraries, modernizing of library management, encouragement of greater community participation in library management, promotion of information and computer technology (ICT) applications, etc. Some of the steps have already been taken to implement the recommendations. However, there is a lack of public library policy at the national level that could give direction to library movement in the country.

Current priorities

The following area has been identified by the Ministry of Culture, Government of India, as a major Thrust Area for the XI Plan (2007–2012): “In the Public Library sector, the main thrust will be on Rural Public Libraries. Existing plan schemes of RRRLF will be enlarged and intensified during the XI Plan.”^[12] With the efforts that are ongoing, it is hoped that this Plan will bring major changes in the public library sector.

School Libraries

Educational system

Introduction. The Indian educational system is regarded as the second-largest system in the world in terms of the

number of students, teachers, and institutions. The system is also highly diversified.

Size. The *All India School Education Survey*, seventh in the series of All India Educational Surveys (AIESs), was conducted with reference date as 30 September 2002. The survey covered 1,031,000 schools functioning in 587,000 villages and around 5300 towns/urban areas. It also provided information about 5.53 million teachers imparting education to more than 200 million pupils in the country. The survey is comprehensive in its scope. There are 883,667 elementary (primary and upper primary), 90,741 secondary schools and 43,869 higher secondary schools in the country.^[32] Thus, the Indian school education system is quite large.

National education policy

Today, the Central Government continues to play a

leading role in the evolution and monitoring of educational policies and programs, the most notable of which are the National Policy on Education (NPE), as updated in 1992 envisages a National System of education to bring about uniformity in education. . .

The National System of Education as envisaged in the NPE is based on “a national curricular framework, which envisages a common core along with other flexible and region-specific components.”^[33] The country is certainly moving towards the goals. The scheme of Navodaya Vidyalayas, aims to promote excellence along with equity and social justice. It has been a trend setter and a great success.

Library facilities

Salient findings of the *Seventh All India School Education Survey* (7th AIES)^[32] regarding library facility in Secondary and Higher Secondary Schools are as follows: 70,090 (77.24%) secondary schools and 39,301 (89.59%) higher secondary schools have library facilities. 73.99% of rural secondary schools have library facility, whereas 84.85% of urban secondary schools have library facility. Similarly, 87.21% of rural higher secondary schools have library facility as against 92.17% of urban higher secondary schools. In secondary and higher secondary schools with a library facility a proportion of 14.98% secondary schools and 41.03% higher secondary schools have full-time librarians. Only 10.07% secondary schools and 12.49% higher secondary schools have part-time librarians. In secondary schools with a library facility, the largest proportion of schools, i.e., 32,615 (46.53%) schools have book strength of up to 500 books. Only 2700 (3.85%) schools have book strength of more than 5000 books. Among higher secondary schools with library

facility, the largest proportion of schools, i.e., 10,126 (25.77%) schools have a book strength of 2001 to 5000 books. Only 7190 (18.29%) schools have a book strength of more than 5000 books.”^[32] As per 7th AISES, “70,090 (77.24%) secondary schools and 39,301 (89.59%) higher secondary schools have a library facility.”

These figures are quite impressive. However, the majority of these libraries do not meet the minimum standards for a school library. Only 46.53% of secondary schools have a library facility housing up to 500 books. This indicates the existing situation.

As per 7th AISES, “70,090 (77.24%) secondary schools and 39,301 (89.59%) higher secondary schools are having library facility.” The figures are quite impressive. The data must be taken with a pinch of salt as the library facilities in a large majority of libraries are inadequate.

The data indicates that a large majority of so-called school libraries do not have a full time librarian. The size of collections in the majority of the libraries is meager. The usual library services provided by school libraries include circulation and some reference service. Library use instruction provided to students is rare.

The best schools in India are mainly those that come under the category of public schools, members of Indian Public School's Conference. These schools have excellent library facilities, usually with individual libraries for the junior and senior classes. Their libraries are computerized with access to the Internet for students and faculty. The collection usually ranges from 30 to 40 thousand volumes, including multimedia collections. They provide a variety of services to students and teachers, such as reference service, circulation of materials and often, some sort of library use instruction is also provided.

Disparities in Facilities and Standards. There are wide disparities in facilities and standards among different types of schools, varying from rural to urban areas and from state to state. Schools in rural areas are a neglected lot. Some states have done better than others. The “public schools” designed after the British models, along with schools called Navodaya Vidyalayas (established by the central government) and Kendriya Vidyalayas (also called central schools) are well-equipped, well-staffed and adequately supervised. However, government rural or municipal schools are ill-equipped, understaffed and poorly supervised. There are a variety of private schools; some are quite good, and others are poor. On the whole, primary education has been in a very bad shape. The above situation is equally applicable to school libraries.

Special Libraries

History

The history of special libraries in India is interrelated with the growth of research institutions and learned

societies. It was only after World War I that learned societies and research institutions began to be established. As a consequence, research activities began to receive a boost at that time. Thus arose the need for improved library facilities. In order to meet the demand for improved library services and facilities, special libraries were established.

Several learned societies or research institutions and their libraries were established as early as the eighteenth century. The Survey of India, The National Survey and Mapping Organisation of the country under the Department of Science and Technology, Government of India, was set up in 1767. It is the oldest scientific department of the Government of India and is India's principal mapping agency. The Asiatic Society, Calcutta, formed in 1784, is an institution of national importance. It is the oldest institution of learning. It has made a tremendous contribution to the growth and development of antiquarian, scientific and literary institutions in India.

Several others were established in the latter part of the nineteenth or early twentieth centuries, before World War I. The Geological Survey of India (GSI), established in 1851, is considered one of the oldest surveys in the World. It is a premier organization of Earth Science Studies with a strength of 2100 geoscientists and technical professionals. The Khuda Bakhsh Oriental Library, Patna, was established in 1875 by Md. Khuda Bakhsh in 1891. Now, this library is an institution of National Importance. The Botanical Survey of India was formally constituted on February 13, 1890. The Survey, with its headquarter at Kolkata, co-ordinates the botanical works of regional centers and botanical explorations. In 1911, the Government of India established the Indian Research Fund Association (IRFA) for the “purpose of sponsoring and coordinating medical research in the country.”

In 1949, It was renamed as the Indian Council of Medical Research (ICMR) with expanded functions. Today, the ICMR is funded by the Government of India through the Ministry of Health and Family Welfare.^[34] It is the apex body in the field of biomedical research.

After World War I special libraries grew more rapidly. The Indian Council of Agricultural Research (ICAR) was established in 1929 along with associated committees for research. ICAR network is a vast one that includes Institutes, Bureaux, National Research Centres and Project Directorates.

It employs, a manpower of about 30,000 personnel. Out of which nearly 7000 consist of research and management personnel. There are thirty-eight Agricultural Universities (SAUs) that employ about 26,000 scientists for teaching, research and extension education.^[35]

Second World War II provided an impetus to the development of scientific and industrial research activities. Thus, the Council of Scientific and Industrial Research

(CSIR) was formed in 1942. This is considered a turning point in the history of scientific and industrial research in India. Today, "it has a network of 38 laboratories/institutes, 39 outreach centers, employing 4555 scientists and 8001 technical persons." CSIR is "amongst the largest R&D organizations in the world for scientific and industrial research"^[36] The Indian Atomic Energy Commission was set up in Aug 1948 in the Department of Scientific Research, Government of India. The Department of Atomic Energy (DAE) was established on August 3, 1954 under the direct charge of the Prime Minister. The Defence Science Organization was set up in 1949. Defence Research and Development Organization (DRDO) was formed in 1958 from the amalgamation of various defense organizations. Today, DRDO has 50 laboratories and is engaged in developing Defense technologies. At present, the Organization employs over 5000 scientists and about 25,000 other scientific, technical and supporting personnel.

The Sahitya Akademi, New Delhi, was formally inaugurated in 1954. Indian Council of Social Science Research (ICSSR) was established in the year of 1969 by the Government of India to promote research in social sciences in the country. Central Institute of Indian Languages was established in 1969, to coordinate the development of Indian Languages. Under it, there are 12 centers and 7 regional centers.

The National Information System in Science and Technology (NISSAT) was launched with the assistance of UNESCO in September 1977. It gave a push to special libraries through the establishment of sectoral information centers in various fields of research. Today, there are 13 sectoral information centers in different areas of science and technology, such as leather technology, food technology, marine science etc., although NISSAT itself ceased operations in 2004.

The Indira Gandhi National Centre for Arts (IGNCA), New Delhi, is a multilingual, multimedia, and multidisciplinary organization. It was set up in 1985, as a Centre in the field of the arts. The Centre is a premier research and academic institute engaged in preservation and documentation of Indian Cultural Heritage. The Kala Nidhi Division of the Centre is "responsible for preservation and dissemination of Indian Cultural Heritage Knowledge Resources."^[37]

The above description shows that it was only after independence (1947) that a large number of scientific laboratories, research organizations and learned societies were set up. In the same time period India has experienced rapid industrialization. This resulted in growing demand for library facilities and services. Thus, special libraries were established to meet growing demand. The majority of them came into being during the last six decades or so.

The institutions and learned bodies that excel in their field of specialization usually have excellent libraries attached to them.

Health sciences libraries

There are three leading libraries specializing in health sciences. These are the National Library of Medicine, the All India Institute of Medical Sciences Library, and the National Documentation Center of National Institute of Health and Family Welfare. All of them are located in New Delhi.

Another institution also has an excellent health sciences related library. The CDRI (Central Drug Research Institute) Library, Lucknow, established in 1951, is a modern and well-managed Library, with a rich collection. It has systematically built up a specialized collection of reading materials consisting of books, periodicals, reference works, serials and various macro and micro-documents in the areas of Biomedical Research and Drugs and Pharmaceuticals. NICDAP (National Information Center for Drugs and Pharmaceuticals), a Sectoral Information Centre on Drugs and Pharmaceuticals came into being in 1977 at CDRI Library.

Food Science and Technology Information Services (FOSTIS) is the central library of Food Technological Research Institute (CFTRI), Mysore and India's National Information Centre for Food Science and Technology (NICFOS). The library is one of the major information resource centers serving the food processing profession with an extensive collection of print and non-print materials.

The National Medical Library (NML) has set up a network of health science libraries in India. It has with the support from WHO, identified six Regional Medical Libraries (RML) and eight Resource Medical Libraries (RL) in the country. A grant-in-aid was given to each RML and RL to strengthen their document collection.^[38]

Law libraries

There are three types of law libraries: academic, judicial and research law libraries.

The leading academic law libraries include Bangalore University College of Law Library, Government Law College (Mumbai) Library, Bombay University Library, Calcutta University Law Library, Delhi University Law Library, Kashmir University Law Library, Madras Law College Library, NALSAR University of Law (Hyderabad), and the National Law School of India University (Bangalore). Delhi University Law Library is regarded as one of the best law libraries in the country.

Recently established National law school libraries are modern, well equipped and provide wide-ranging services. Libraries attached to NALSAR University of Law (Hyderabad), National University of Judicial Sciences (Kolkata), National Law University (Jodhpur), Hidayatullah National University of Law (Raipur) and Gujarat National Law University (Gandhinagar) have good legal collections.

National Law School of India (NLSIU), Bangalore, has one of the best academic law libraries in the country. It has set up a state-of-the-art digital library. The library has computerized its library facilities for house keeping and information retrieval. It possesses modern gadgets with wi-fi Internet connectivity and modern audio-visual equipment with teleconferencing capability. In addition, the library provides the facility access to a library portal through which the users can access contents of the current journals, the holdings of current print journals, e-journals, special collections of the library, and information about the library, its staff and services.

Judicial libraries include the Supreme Court Library (New Delhi), High Court Libraries in the states (many of these have good legal collections), bar association libraries attached to the Supreme Court and the high Courts. The Supreme Court Library is the largest law library in the country. Other leading judicial libraries include Calcutta High Court Library, Karnataka High Court Library (Bangalore) and Madras High Court Library. Bar Association libraries serve their lawyer-members and are financed by membership subscription.

Organizations involved in legal research maintain their own libraries. Indian Law Institute Library (New Delhi) is a major library having a rich collection. The Legal Information Resource Centre has been established for

“retrieving legal information from Indian and foreign Web sites of the Apex Courts, International Courts, Legal Information Institutions, Law Commissions, Human Right Commission. The library subscribes to about 150 legal journals, national and international, and receives nearly 200 periodicals as gifts or in exchange... The library currently houses a collection of 70,000 books and periodicals. In addition, has 25 CD-ROM titles.”

It provides Indexing of Indian Legal Periodicals, Indexing of Indian Legislation, Newspapers Clippings Service, Internet Service, Documentation and Bibliographical Services. It has an online library catalog.^[39] Besides the above libraries, National Law Institute (Bhopal) Library is another good library.

An example of a modern special library

The Institute for Plasma Research (IPR) Library, Gandhinagar, is a good example of a modern special library. It is a state-of-the-art library. It has a rich collection, helpful staff, wide-ranging services, a soothing ambience, and an atmosphere conducive to scientific research. It gives access to more than 2200 e-journals. The Library has designed a Web site that serves as a gateway to plasma information and provides links to the OPAC, electronic journals, local resources, web resources, etc.^[40]

Conclusion

Special libraries are

primarily, a twentieth-century phenomenon in India. Although a handful existed in the nineteenth century, the majority of these libraries came into being only during the last five decades or so. They are largely concentrated in major towns like Bangalore, Calcutta, Delhi, Hyderabad, Mumbai, and Madras. On the whole, special libraries have succeeded in building a better image than academic and public libraries. They have shown initiative and done better than other types of libraries. They have been forerunners in computer application in Indian libraries.^[41]

Thus, special libraries in India have been trendsetters in many ways.

Digital Library Collections and Services

Introduction

In India, a number of libraries, information centers and other institutions have initiated digital library projects by creating databases and e-journals, or by digitizing their own valuable collections. Some of these are described in the next few paragraphs.

General

The Digital Library of India (DLI) is a major project that aims to “digitize all the significant works of mankind.” The DLI has three sites which are mirrors of each other, IIIT-H being one of them, as given below:

<http://www.new.dli.ernet.in/index.html.en>
<http://dli.iiit.ac.in/>
<http://www.dli.cdacnoida.in/>

DLI covers primarily books.^[42] Though some newspapers and manuscripts are mentioned in one of the sites, they actually point to the external site of the respective newspapers. That is why, what is shown as “manuscripts” or “journals” is really not correct. It is a project hosted by Indian Institute of Science, Bangalore, in cooperation with CMU, IIIT, NSF, ERNET, and MCIT, for the Government of India and 21 participating centers. The mission is to “create a portal for the Digital Library of India which will foster creativity and free access to all human knowledge.” Indian Institute of Science, Bangalore, is coordinating the Digital Library of India project along with Carnegie Mellon University.^[43]

The UGC-Infonet Digital Library Consortium was formally launched in December, 2003. The Consortium provides current as well as archival “access to more than 4500 core and peer-reviewed journals and nine bibliographic

databases from 23 publishers and aggregators in different disciplines.” The program is funded by the UGC and administered by the INFLIBNET (Information and Library Network) Centre, Ahmedabad.^[44]

Vidyanidhi is India’s premier “Digital library initiative to facilitate the creation, archiving and accessing of doctoral theses.” Vidyanidhi Database offers “access to more than 1,00,000 Indian theses metadata records. . . Vidyanidhi provides access to 6500 Full Text Theses Database.” It is supported by NISSAT, DSIR, Government of India, the Ford Foundation and Microsoft India.^[45]

INLIBNET Centre under “Electronic Theses and Dissertations Project,” hosts a bibliographic database of 200,000 dissertations from about 200 Indian universities going back to 1905. Panjab University Digital Library provides access to Library OPAC, online journals, online books, e-reference sources, theses and dissertations, conference proceedings, UN and other information agencies publications, subject gateways, INFLIBNET databases, DELNET databases, LIS portal and miscellaneous.

Indira Gandhi Memorial Library, University of Hyderabad, is one of the first libraries in India to start digitization of books. Since 2002, the library has digitized around 250,000 pages, primarily theses and dissertations, as well as 300 books in English and Indian languages.^[46]

University of Delhi has initiated a repository called University of Delhi Eprint Archive. This repository uses GNU Eprints open repository software. Many other universities have also created institutional repositories.

Science

e-Prints is a repository at Indian Institute of Science (IISc), Bangalore, that collects, preserves and disseminates in digital format the research output created by the IISc research community (depository of their preprints, post prints and other scholarly publications). It uses a web interface, and organizes these publications for easy retrieval.^[47]

The National Centre for Scientific Information (NCSI), Bangalore provides a

variety of electronic information services to the Institute’s scholars. These include: intranet and Internet access to world’s leading bibliographic databases; gateway services for electronic journals and open access resources on the Internet; customized web access (‘MySciGate’); IISc e-print archive; and document delivery services.^[48]

NISCAIR (New Delhi) has already started the work on the project known as National Science Digital Library (NSDL). It is first of its kind in the country that aims at providing access to digital resources for students.

There are a number of digital repositories of scientific materials at leading scientific institutions using DSpace. These include the Indian Institute of Astrophysics, Bangalore; Raman Research Institute, Bangalore; National Chemical Laboratory, Pune; and the National Institute of Oceanography, Goa.

Medicine

Bioinformatics digital library at Jaypee University of Information Technology, Solan (HP), provides a centralized access for existing resources in bioinformatics.

Traditional Knowledge Digital Library (TKDL) for Indian Systems of Medicine is a collaborative project of the National Institute of Science Communication and Information Resources (NISCAIR), the Council of Scientific and Industrial Research, the Ministry of Science & Technology and Department of AYUSH, and the Ministry of Health and Family Welfare. The project is being implemented at NISCAIR.^[49]

Engineering and technology

The Ministry of Human Resource Development (MHRD) set up the Indian National Digital Library in Engineering Sciences and Technology (INDEST) Consortium.

The Ministry provides funds required for subscription to electronic resources for^[33] institutions including IISc, IITs, NITs, IIMs and a few other centrally-funded Government institutions through the consortium headquarters set-up at the IIT Delhi. Besides, 60 Government or Government-aided engineering colleges and technical departments in universities have joined the Consortium with financial support from the AICTE.

Later on, it was renamed INDEST-AICTE Consortium.^[50]

The Indian Institute of Technology, New Delhi (EPrints @IIT Delhi) provides access to Online courseware, older volumes of journals, more than 500 theses and dissertations are available in the repository. There are facilities for submitting material to the repository.

The Indian Institute of Technology, Bombay repository provides bibliographic information and abstracts for dissertations from 1965 onward. The masters thesis database has bibliographic information and abstracts from 1999 onward. There are more than 3000 full text theses and Dissertations available in the ETD database.

Nalanda, the Digital Library initiated in 1999 at the National Institute of Technology, Calicut, is one of the largest digital libraries in the country. The repository contains theses and dissertations, course materials, articles, and annual reports. It serves members of the campus with value added services in all the areas of Science/Engineering/Technology.

Social sciences

The Archives of Indian Labour is a unique digital project initiated at the V.V. Giri National Labour Institute (NOIDA, UP), in collaboration with the Association of Indian Labour Historians (AILH). The archive, is a prime repository of labor related records in the country, that aims at preservation of rapidly decaying documents and material on labor.

A Digital Library of electronic publications was set up in 1997, at the Parliament Library (New Delhi), to serve the information needs of members of the Parliament and officers of Lok Sabha Secretariat. The digital collections consist of reference books (atlases, directories etc), reports, e-journals, etc.

Humanities

India has one of the oldest and largest collections of manuscripts in the world. A significant proportion of them have not been preserved scientifically. National Mission for Manuscripts was established specially to tackle the problems related to manuscripts. The mission has already started a pilot project for digitizing the manuscripts in five states.^[51] The National Library has undertaken a project for Digitization (Down the memory lane). The scanning and archiving of rare and brittle books and other documents on compact disc has been under taken. English books and documents published before 1900 and Indian publications of pre 1920 are being digitized. Up to now, 6600 selected books in Indian and English languages have already been scanned and stored on 548 CDs.

The Centre for Development of Advanced Computing (C-DAC) Digital Library of Art Masterpieces is “the first initiative of its kind in Asia. It will digitize 200 rare paintings of Rabindranath Tagore and Amrita Shergill from the National Gallery of Modern Arts (NGMA).”^[46] The Indira Gandhi National Centre for the Arts (IGNCA), New Delhi, in collaboration with the Ministry of Communication and Information Technology, initiated a project, KALASAMPADA (Digital Library: Resources of Indian Cultural Heritage), for the development of databank of cultural heritage. Kalasampada facilitates the scholars (users) to access and view the materials including over 200,000 of manuscripts, over 100,000 slides, “thousands of rare books, rare photographs, audio and video along with highly researched publications of the IGNCA, from a single window.”^[52] It is a rich resource of information on Indian art and culture.

Other subjects

Indian Institute of Management, Kozikode (IIM-K), has established a repository for documents limited to the IIMK research community. They can submit preprints,

postprints, and other scholarly publications for archiving. The Librarian's Digital Library is a repository set up at the Documentation Research Training Centre, Indian Statistical Institute, Bangalore. It aims to cover material of interest to librarians world-wide. The repository contains articles, theses and dissertations, presentations, multi-lingual documents, photographs, etc.

Information Science as a Discipline and Profession

Discipline

Today, Information Science is considered as a discipline in its own right, an interdisciplinary area of study. Its growth in India has been rather slow. There are very few information schools. They are coming into being slowly. There are only a few institutions conducting courses in information science as given below:

Birla Institute Of Technology, Ranchi (Jharkhand)

The Department of Information Science, Mersa, Ranchi, offers courses leading to an M.Sc. (Information Science) (two-year integrated program) (1993–) and a Ph.D.

Documentation Research and Training Centre, Bangalore (Karnataka), Indian Statistical Institute

From 2008, DRTC has introduced MS (LIS), that is Master of Science in Library and Information Science, that offers comprehensive instruction in the theory and practice of documentation and information science. DRTC also conducts a Research fellowship program, where the emphasis is on special libraries.

National Institute of Science Communication and Information Resources (NISCAIR) (formerly INSDOC), New Delhi

The Education and Training Division of NISCAIR, offers a two-year course leading to Associateship in Information Science (AIS) since 1976. AIS is a two-year program equivalent to Master's degree in Library and Information Science, recognized by Government of India and many Indian Universities.

University of Madras

In 1995, the Department of Library and Information Science, University of Madras, replaced its Master of library and Information Science, with a Master of Science (M.Sc.) in Library and Information Science. In 2004, the Department of Library and Information Science, University of Madras, was renamed Department of Information Science, as the first of its kind. Master of Library and Information Science course was replaced by “Master of Science” in Information Science (that is M.Sc. [Information Science]) beginning in academic session 2004–2005. It has also a provision for Ph.D. in Information Science.

The University of Mysore

Mysore, has established a new generation centre called the International School of Information Management

(I-SiM). ISiM, is a new age school for the knowledge Society. ISiM offers the following programs:

M.Tech. in Information Systems & Management (started in 2008), Doctoral Degree Program (Ph.D.) in Information Systems & Management, Executive Education Programs, Corporate Training.

Impact of information science on library science

In the 1970s, library schools introduced topics from information science. The UGC Panel on Library and Information Science (1982), recommended that library schools might consider changing the nomenclature of library science courses named B.Lib.Sc. and M.Lib.Sc. to BLISc. (Bachelor of Library and Information Science) and MLISc. (Master of Library and Information Science) respectively, so as to reflect the changes introduced in their curriculum. As a result, Library Schools have changed the names of their degrees.

At one time, a library school in India was generally called a "Department of Library Science." Beginning in the late 1970s, most were renamed as a "Department of Library and Information Science," as most of the library schools are called today. Thus, traditional library schools are teaching both library science and information science and their names and their degrees include the term "library and information science."

Profession

Information science as a profession is emerging slowly. The Society for Information Science (SIS) was formed during 1975, to look after the interests of people in the profession.^[53] SIS is an all India professional body devoted to encouraging interaction among information professionals, scientists, managers, and users of information. Many of the members are also members of library associations. Another association that looks after the interests of information professionals is IASLIC (Indian Association of Special Libraries and Information Centres). It has created Special Interest Groups (SIGs) to bring together persons of common interests.

Librarianship as a Discipline and Profession

Discipline

Today, librarianship is a full-fledged discipline in its own right. It is recognized as a subject of study and research, worthy of study at the university level at par with other disciplines. There are separate library schools at university, college and institute level, often called Department of Library and Information Science. Librarianship as a discipline is taught at universities, colleges and institutes with curricula leading to the following degrees:

- Bachelor of library and Information Science
- Master of Library and Information Science
- M.Phil.
- Ph.D.
- Post-doctoral degree

The trend is toward establishing two-year integrated Master of Library and Information Science, and abolishing the Bachelor's degree. In recent years, there is also a trend toward offering specialized postgraduate courses. For professional jobs, a degree in library and information science, from a library school affiliated to a university, is a basic requirement. Thus, librarianship as a discipline is well established.

Profession

A profession is an occupation, vocation or career where specialized knowledge of a subject, field, or science is applied.^[54]

To become a library professional in India, one is required to possess a degree in library and information science, obtained from a library school attached to a university or college/institute (affiliated to a university). Standards for library education have been formulated by the University Grants Commission (UGC), a coordinating and grant-giving body at the national level. There is an increasing emphasis on continuing education. There is a trend toward providing internship in libraries. For the job of an assistant librarian in a university library or a college librarian, one is required to pass a UGC Net or state level test. In India, the provision of "Licensed practitioners" has not been applied. Joint Council of Library Associations of India (JOC LAI) has formulated a Code of Ethics for the library profession in India. From the above, it follows that librarianship in India fulfills most of the major characteristics of a profession.

Education for LIS

History

William Alanson Borden (1853–1931), an American-trained librarian, was invited by His Highness the Maharaja Sayajirao III, Gaekwar of Baroda (1862–1939), to establish libraries in the princely State of Baroda. Borden started a training program in the State in 1911. It was the first library school to be established in India. Thus, the history of library education in India began in the year 1911. In 1937, the University of Madras introduced, effective from July 1937, a one-year postgraduate diploma course. This was the first full-time course conducted in India, another land mark in the history of library education. This was also the first diploma course conducted by a university.

The Department of Library Science at the University of Delhi initiated a postgraduate course in 1947. In 1948, the University of Delhi became the first university in India to institute a degree course in Library Science (a post-graduate course of study). In 1949, the first batch of students completed the two-year study program. They received their B.Lib.Sc. (Bachelor of Library Science) degrees in 1949. In 1949, a two-year course leading to the award of M.Lib.Sc. (Master of Library Science) degree was introduced to replace the previous program of B.Lib.Sc. The first cohort of students received their M.Lib.Sc. degree in 1951.

The University of Delhi was the first university in the British Commonwealth to introduce this course at the master's level. In 1951, it also became the first university in the country, as well as in the British Commonwealth to introduce doctoral studies in library science by framing regulations for such a doctoral program. A Ph.D. candidate was registered at the University of Delhi in the 1952–1953 academic session. The first Ph.D. in library science was awarded in 1957 to D.B. Krishna Rao by University of Delhi under the guidance of Dr S.R. Ranganathan.

The period of growth of LIS (Library and Information Science) education started in the early 1960s, when there was sudden growth of library education. Many new library schools were started in the 1960s. Realizing the need for standardization of syllabi, examination, qualifications of teachers, etc in the field of library science, UGC in 1961, appointed a Review Committee, under the Chairmanship of S.R. Ranganathan. The Committee submitted its report in 1965.^[55] The report made many useful and far reaching recommendations regarding syllabi, standards, etc. This report is a landmark in the history of library education in India.

The Indian Association of Teachers of Library and Information Science (IATLIS) was founded in 1969. It has played a significant role in LIS education.

UGC set up in July 1977, a Specialist Panel, called UGC Panel on Library Science. Its aim was to advise the Commission regarding measures for improvement of standards and facilities for teaching and research, and for the development of interdisciplinary and multidisciplinary programs, etc.

The period of modernization started in the early 1990s. Library schools started revising their curriculum, introducing courses on computer application in libraries, and also included substantial amount of information science. It is also during this period that the library schools began to establish computer laboratories for giving hands-on experience to their students.

Growth of library schools

In 1947, at the time of independence, there were just five library schools at the university level. By the end of 1950s, there were 13 such schools. According to the *Directory of*

library and information schools in India published in 1988, that covers information about 93 schools and other institutions in India offering training in library and information science at different levels, there are 66 university departments that offer a bachelor's degree in library and information science, 38 of which also offer a master's degree in library and information science, and four of which offer a master of philosophy degree in library and information science. There are 19 schools that offer a doctoral program in library and information science.^[56] Today, there are 167 library schools (including information schools) conducting postgraduate courses (121 university level library schools and 46 colleges and institutes conducting library and information science programs including one organization, namely, NISCAIR (formerly INSDOC) that offers two-year Associateship in Information Science). There are 41 universities offering library and information science courses through correspondence or distance education. 129 universities are offering bachelor's degree including four offering a Post-graduate Diploma in Library Automation and Networking and one a Diploma in Health Science Librarianship; 118 offer master's degrees including 37 library schools that conduct two-year integrated master's program; 22 offer M.Phil. degree; 72 offer Ph.D. degree (based on data gathered by the present authors from various sources).

Levels of courses

Basically, Indian library Schools are providing library education at four levels:

1. B.LISc. (Bachelor of Library and Information Science)
2. M.LISc. (Master of Library and Information Science)
3. M.Phil (Master of Philosophy)
4. Ph.D.

Now, most of the universities award Bachelor of Library and Information Science (B.LISc.) degree. There are 118 library schools that are offering master's degrees. Out of these, 37 offer two-year integrated programs.

It was a guideline from UGC to universities that recommended introduction of M.Phil. program as a research degree between Master's and Ph.D. degrees. As a result, some library schools introduced M.Phil.

There are more than 50 Ph.D.s being produced annually. Ph.D. programs are now well established.

Admission requirements

For admission to bachelor's degree in LIS or two-year integrated master's course, the usual minimum qualification is a B.A./B.Sc. Some library schools, they conduct an admission test and/or interviews for admission, in addition to minimum academic qualifications prescribed for the

purpose. For admission to one-year master's degree course, bachelor's degree in library and information science is prescribed. Many library schools conduct an admission test. Some schools have also prescribed professional experience as an essential requirement as well.

Qualifications for admission to M.Phil. and Ph.D. vary from school to school. To obtain a Ph.D., 2–3 years of residence is essential in many universities. In some universities, only a short period of residence is required.

Course content (outline)

Typical course content (outline) for Master of Library and Information Science (two-year integrated course) at University of Mysore is given below:

Foundations of Information Science and Society; Fundamentals of Information Technology; Information organization; Personality Development and Communication Skills; Content Organization (DDC)—Practicum; Information Resources; Organizing Information Resources-I; Information Retrieval Systems; Information Technology Skills—Practicum; Content Organization (UDC)—Practicum; Managing information Resources-II; Managing information and information centre; Data communication and networking; organizing information resources—Practicum I; Technology for information management—Practicum; Digital libraries; Information resources, systems and services; Research methods and project management; Organizing information resources—Practicum II; Project.^[57]

The above two-year integrated program is spread over four semesters. The stress is on information science and technology. There is less stress on traditional library science.

The Indira Gandhi National Open University (IGNOU) is one of the premier institutions in the country providing Library and Information Science (LIS) courses through distance education. An outline of the syllabi is given below:

Syllabus for B.LISc.

Library and Society; Library Management; Library Classification Theory; Library Classification Practice; Library Cataloging Theory; Library Cataloging Practice; Reference and Information Sources; Information Services; Information Technology: Basics.

Syllabus for M.LISc.

The Program has been designed and developed keeping in view the handling of information rather than library materials as a whole. The program consists of six core courses, one project and six electives (out of which two have to be selected). Information, Communication and Society; Information Sources, Systems and Services; Information

Processing and Retrieval; Management of Library and Information Centres; Fundamentals of Information Communication Technologies; Information Communication Technologies: Application; Project.

Electives (any two are to be chosen by the learner)

Preservation and Conservation of Library Materials (Elective); Research Methodology (Elective); Academic Library System (Elective); Technical Writing (Elective); Scientometrics and Informetrics (Elective); Public Library System and Services (Elective).

The school follows a multi-media approach for instruction. The students are offered self-instructional learning course material packages along with:

- Assignments for assessment and feedback
- Supporting audio–video programs
- Face-to-face interaction with academic counselors at Study Centers
- Practical work at designated institutions
- Telecast of Video Programmes on National Network DD1 and EDUSTAT
- Broadcast of Audio Programmes by All India Radio (Selected Stations)
- Teleconference sessions through Gyan Darshan.
- Interactive Radio Counselling Programmes.^[58]

IGNOU conducts BLISc. (one-academic year) and MLISc. (one-academic year) courses, as well as PGDLAN (Post Graduate Diploma in Library Automation and Networking) (one-academic year) through distance mode. BLISc. and MLISc. courses at IGNOU provide a combination of library science and information science. It has introduced many innovative approaches for providing distance learning to the learners. The courses offered by IGNOU are very popular. They have set new trends in multi-media based LIS education in the country. In 2008, IGNOU has introduced MLISc. online. The course was inaugurated in June. This the first online course in LIS to be introduced in India.

Methods of teaching and evaluation

There are a variety of methods of teaching being used in Indian library schools. However, the lecture method predominates.

Usually, evaluation is based on performance on a written examination. The students are tested through written examination at the end of the year or at the end of each semester. The written examination is based on essay type questions. There may be some questions requiring writing of short notes or questions involving objective questions or multiple-choice questions. The examination may last for 2–3 hours.

Oral examinations are used to assess dissertation/ project report, sessional work, etc. Increasingly library schools are introducing internal assessment. Internal assessment is done by the teacher teaching the course, based on written assignments, seminar, practical work, etc.

As regards internship, the system varies from library school to library school. In some library schools, it is a compulsory part of the course.

Accreditation

There is no system of accreditation of library schools by a national organization in India. UGC, Association of Indian Universities, and the Ministry of Human Resource Development (Government of India) have played a definite role in the matter of equating degrees within India and degrees awarded by foreign universities. Each university has a specified procedure to equate degrees. Usually, they follow the advice of higher bodies as mentioned above. The National Assessment and Accreditation Council (NAAC) is an autonomous body established by the University Grants Commission (UGC) of India to assess and accredit institutions of higher education in the country. It has started the process. In due course of time, library schools will also be covered. However, courses conducted by IGNOU have been accredited by the Council responsible for accreditation of courses run by the open universities.

Continuing education

The University Grants Commission, in pursuance of the National Policy on Education 1986 and its program of action, had set up 57 Academic Staff Colleges (ASCs) in different Universities/Institutions in the country. These Academic Staff Colleges conduct specially designed Academic Staff orientation programs for newly appointed lecturers and refresher courses for in-service teachers. These programs have proved to be quite useful for LIS teachers and librarians working in universities and colleges, coming under the purview of UGC.

In regards to librarians and teachers of LIS, library associations, library schools, institutions like DRTC, NISCAIR, DESIDOC, etc. also conduct continuing education programs for their benefit.

Conclusion

There has been a proliferation of library schools. Emergence of such a large number of library schools (i.e., 167) has led to an oversupply of library professionals. Library schools are beginning to regularly revise their courses, keeping in mind the latest developments in LIS as well as in ICT. Reports of the UGC Curriculum Development Committee^[59,60] have proven to be quite useful in this regard.

Professional Associations

Introduction

There are a variety of professional organizations and associations in India that are organized at national, state, and local levels. They number more than 200, if students' associations are included. Some of the major organizations are described here.

Indian Association of Teachers of Library and Information Science

IATLIS is a professional association of about 500 teachers and library professionals. Since its inception in 1969, IATLIS has been involved in issues of LIS Education in India, especially curriculum development, teaching methods, infrastructure, teachers' training, etc. It looks after promotion of the professional interests of LIS teachers. It conducts national seminars, workshops, training programs etc and brings out *IATLIS Communications* (official journal) and publishes pre-conference volumes and other books.

The Indian Library Association

At the second session (September 13, 1933) of the first "All India Library Conference" held at Calcutta during September 12–14, 1933, a resolution was passed, that led to the formation of Indian Library Association. The objectives of the Association:

1. Promotion of library movement and improvement in library services in all its aspects in India
2. Promotion of library science education and improvement in the training of librarians in India
3. Establishment of libraries, documentation and information centers and assistance in their establishment and working
4. Promotion of appropriate library legislation in India
5. Providing a common forum to all persons engaged or interested in library and information work by holding conferences and meetings for discussion of professional, technical and organizational issues
6. Accreditation of institutions imparting library and information science education and training
7. Promotion as well as formulation of standards, norms, guidelines, etc. for management of library and information systems and services^[61]

In 1933, ILA had 70 members and in 2006, it had 7218 members. In a large country like India, where around ten thousand professionals (degree holders) are estimated to be produced every year and the total number of professionals may be around 200,000; the membership figure is low. This is a matter of concern.

The ILA has a president, six vice-presidents, a general secretary and an executive committee. It is organized so as to operate through 11 sectional committees. Major activities of ILA include sponsoring conferences, seminars, conventions, training programs, lectures, etc. It organized an International Conference on Ranganathan's Philosophy at New Delhi in 1985. In the same year, in collaboration with Sarada Ranganathan Endowment for Library Science, it organized the Second Regional FID Conference. ILA hosted the 1992 IFLA Conference at New Delhi. It was a great success. It brings out *ILA Bulletin* and *ILA Newsletter* on a regular basis. It publishes professional tools, conference and seminar proceedings, and annual reports.

ILA was founded in 1933. Thus, the year 2008 was the Platinum Jubilee Year of ILA. It was being celebrated by ILA through various programs. The year 2010 is the Centenary Year of Library Movement in the country. Plans for celebration are underway. ILA has been in the forefront, in taking up issues facing Indian librarianship, such as salary scales, library legislation, status of librarians, etc.

IASLIC

A meeting of librarians was held on September 3, 1955 at the Lecture Hall of the Indian Museum, Calcutta. This is the meeting in which the Indian Association of Special Libraries and Information Centres (IASLIC) was formally established.^[62] The major objectives are:

To improve the quality of library and information services and documentation work;

To coordinate the activities of and to foster mutual co-operation and assistance among the special libraries, scientific, technological and research institutions, learned societies, commercial organisations, industrial research establishments, as well as other information and documentation centres to the fullest extent;

To serve as a field of active contact for libraries, information bureaus, documentation centres, scientists, research workers, specialists, and others having common interest;

To improve the technical efficiency of the workers in special libraries, and information and documentation centres; and to look after their professional welfare;...^[63]

IASLIC publishes monographs and other types of documents. *IASLIC Bulletin* is the official journal, published quarterly since 1956 and The *IASLIC Newsletter* has been published bimonthly since 1966. The Association conducts short-term courses, workshops, round tables, seminars etc. It provides consultancy services. It has created Special Interest Groups (SIGs) to bring together persons of common interest. In addition, it organizes conferences, seminars, lectures and study circles.

State level associations

There are a large number of associations at the state level. Each state and union territory has a separate association, sometimes even more than one. The leading associations include Andhra Library Association, Bengal Library Association, Delhi Library Association, Madras Library Association, etc.

Conclusion

The National Library, Kolkata, is the largest single library that serves as the depository as well as the repository of all the published material of India. In addition, there are two other national libraries, namely, the National Science Library and the National Medical Library. India is a large country having one of the largest education systems in the world. Academic and research libraries are under tremendous pressure due to lack of resources and increasing number of students, research scholars and faculty to be served by them.

Public libraries in India have made much progress after independence. However, their penetration is inadequate. They have yet to reach the masses spread over remote corners of the country especially in rural areas.

School libraries form the weakest link. Public schools and schools run by central government are doing a better job in providing good school libraries. Schools located in metropolitan towns have better libraries. However, libraries attached to rural schools need a massive reform.

Special libraries exist in great variety and have done fairly well compared with other kinds of libraries. There are many special libraries, especially in the field of science and technology, that are well-equipped to provide highly satisfactory services to meet the needs of their users.

Today, there are 167 library schools (including information schools). There are 41 universities offering LIS courses through correspondence or distance education. 118 schools offer master's degree and 72 of them offer Ph.D. program. Thus, India has a fairly large system of LIS education.

ARCHIVES AND ARCHIVAL SCIENCE

Introduction

The valuable history of India is embedded in millions of records that exist in the form of manuscripts, inscriptions, and other kinds of records. Unfortunately, most such materials have yet to be preserved and restored in a scientific manner. However, efforts are being made in this direction.

Archival studies has been a rather neglected field in India. It has fewer than 100 archives. However, the situation is changing. Industrial houses, universities and research institutions are beginning to set up their archives.

Legislation Concerning Archives and Regulations That Relate to Record Keeping

The Public Records Act was passed by the Indian Parliament in 1993 to regulate the Management, Administration, and Preservation of Public Records of the Union Government, Union Territories, Public Sector Undertakings, Statutory Bodies and Corporations, Commissions and Committees constituted by the Union Government or Union Territory Administrations. The functioning of the Act is given in detail under the Public Records Rules, 1997.^[64] Under the Act, the National Archives of India (NAI) has been given the major responsibility regarding management, administration, and preservation of public records.

National Archives and Services

The National Archives of India, New Delhi

The National Archives of India (NAI), New Delhi, is the premier organized record repository in India. It was set up in March 1891 at Calcutta (now called Kolkata) as the Imperial Record Department. It was shifted to New Delhi after the transfer of the Capital from Calcutta to New Delhi in 1911. It has set up four regional repositories in Bhopal, Bhubaneswar, Jaipur, and Pondicherry.

Activities. NAI is the repository of the noncurrent records of the Government of India and holds them in trust for the use of administrators and scholars. It is an Attached Office of the Department of Culture under the Ministry of Tourism and Culture. NAI performs a wide range of activities. Its main activity is concerned with "Preserving the records of Government of India in its custody, and regulating the Access and Record Management policy of the Government" as per the provisions laid down in Public Record Act.^[65]

Holdings. The holdings of records in the National Archives

run into 40 Kms. of shelf-space area and are in a regular series from the year 1748 onwards, though there are stray records of the earlier period as well. . . Apart from records on paper, we also have records on palm leaf, birch bark, parchment etc. The records are broadly of four categories: Public Records, Oriental Records, Manuscripts and Private Papers. These records throw light on the activities of the later Mughals, the East India Company and British

Rule and the emergence and growth of the freedom struggle in India. They also shed valuable light on our social, political, economic and cultural life. In addition, there is a rich collection of Private Papers and more than 7500 microfilm rolls of records acquired from different countries. . .

The total holdings in the custody of NAI comprises of 3,875,332 files; 64,221 volumes; 110,332 maps and cartographic items; 3601 Bills assented to by the President(s) of India; 1065 Treaties; 2442 rare manuscripts. NAI has a wide ranging and an extremely rich collection, including government records and private papers especially records of national importance that are invaluable to research scholars.^[66]

Services. NAI offers xeroxing, microfilming and photocopying facilities and also undertakes search for records on behalf of scholars and institutions on payment. Facilities for online access to records are available from the Research Room of the Department.

Finding Aids. To facilitate retrieval of information, there are various types of finding aids that have been designed. These include Guide to Records, Indices, Press Lists, Calendars, Descriptive Lists, Subject Lists etc.

Eleventh Five-Year Plan. The report of the Working Group on Art and Culture of the Ministry of Culture, Government of India for the 11th five-year plan (2007–2012) recommended "six new schemes to be taken up by National Archives of India during the 11th Five Year Plan. These schemes are aimed at modernizing the National Archives and enhancing the quality of services besides conservation of public records."^[67] The work on some of the schemes has already started.

Other national repositories

Other national repositories include:

Archives of Indian Labour, Noida (UP)
Indira Gandhi National Centre for the Arts, New Delhi^[68]
National Library, Kolkata^[69]
Nehru Memorial Museum and Library, New Delhi
Parliamentary Museum and Archives, New Delhi
Reserve Bank of India Archives, Pune

State archives

Some of the leading state archives are listed below:

Gujarat State Archives, Gandhinagar. Gujarat State Archives have been created from records (files and manuscripts) of several Princely States and Political Agencies of British India. The records holdings of the Gujarat State Archives are broadly divided into two series, namely, the records of the former princely states and the secretariat records. Gujarat is very rich in terms of archival wealth.

The Karnataka State Archives, Bangalore. The Karnataka State Archives is a repository of non-current records of the Government. It also has Ecclesiastical (Religious) Archives, Business Archives, Industrial Archives and other Private Archives. Work has been initiated to computerize all the required information about the documents. The State Archives has undertaken a program called “Oral History.”

The Kerala State Archives Department, Thiruvananthapuram. It is the custodian of all public records (non-current) of permanent value of State Government and its various departments. The records received from private individuals and institutions are also being maintained in the department.

Punjab State Archives (Patiala and Chandigarh). Punjab State Archives have nearly 1 million records in its custody. “Punjab archives have illustrated manuscripts, including copies of *Ain-I-Akbari*, *Zaffarnama* of Guru Gobind Singh, *Shahnama* of Firdausi, *Adi Granth* of 1666, tales of *Laila Majnu*, rare Tibetan palm-leaf manuscripts etc.”^[70] Punjab Archives has inherited a large number of records from the various princely states that got merged into the present Punjab.

The Tamil Nadu Archives, Chennai. Tamil Nadu Archives and Historical Research is regarded as one of the biggest Archives and Research Institutions in South East Asia. It is a rich resource of records going back to the seventeenth century. It houses

...the records of various Departments of the Secretariat, erstwhile Board of Revenue, a few Heads of Departments, pre-mutiny records of Collectorate and District Courts and records of defunct Departments. The records dating back to 1657 A.D. (Dutch Records) are preserved in this Archives.^[71]

West Bengal State Archives, Kolkata. The

collections include East India Company’s administrative records from 1770 to 1858, some Persian and Bengali records from 1624. Dutch records relating to Chinsurah from 1702 to 1827, some Danish records on Serampore, records of the Secretariat Departments and records of the Crown period 1858–1947 and indices.^[72]

College and university archives

There is an increasing awareness in academic institutions about the value of archives. Therefore, a number of colleges, universities and other academic institutions have set up their archives. Some of these are described below:

Indian Institute of Astrophysics Archives, Bangalore

Indian Institute of Astrophysics archives has important collections, “some of which are more than 200 years old.”^[73]

Indian Institute of Science Archives, Bangalore

The Institute has established an Archives and Publications Cell to collect, catalog and preserve all documents of relevance to the Institute.

Jawaharlal Nehru University, New Delhi

The Archives on Contemporary History set up in 1970 at the Jawaharlal Nehru University, New Delhi, is a “repository of variety of materials on the leftwing movement in India.”^[74]

Jesuit Madurai Province Archives, Sacred Heart College, Kodaikanal

Jesuit Madurai Province Archives has a large collection of rare books, manuscripts, personal papers, antique instruments (pocket watches used by missionaries, old French medical instruments) etc.^[75]

Maulana Azad Library, Aligarh

Maulana Azad Library of Aligarh Muslim University has a wide-ranging collection consisting of books, periodicals, pamphlets, manuscripts, paintings and photographs. The Library “performs the functions of a National Library so far as its collection of Oriental manuscripts are concerned. It is because of these rich collections of immense research value that this Library is reckoned among major libraries of the world.”^[76] The library has a rich collection of manuscripts, rare books and early paintings.

Film archives

The mission of the National Film Archive of India is

to safeguard the heritage of Indian Cinema for posterity and act as a centre for dissemination of a healthy film culture in the country. Promotion of film scholarship and research on various aspects of cinema also form part of its Charter. Familiarizing foreign audiences with Indian Cinema and to make it more visible across the globe is another declared objective of the Archive.

The National Film Archive of India acquires

National and State Award winning films, Indian Panorama films, Box-office hits and films shown in international film festivals. Film adaptations of famous literary works, films

representing different genres of Indian Cinema, news-reels, documentaries representing the categories mentioned above also find their way to the Archive. Selected foreign films representing national cultures, different genres and landmark works of major filmmakers from different countries are also acquired and used for archival and research purposes.

Books and periodicals covering

Indian and World Cinema, Festival Publications, ancillary material like Song booklets, photographs, wall posters, pamphlets, folders, disc records and other memorabilia on Cinema are also collected and preserved by the Research & Documentation Section.

The treasures of the NFAI's film collection include "the surviving fragments of the films of D.G. Phalke and Baburao Painter, the silent films of Himansu Rai and Franz Osten, a representative collection of films of the great film companies and studios of the 1930s and 1940s. . ."[77] NFAI has a rich and unique collection about Indian Cinema, not to be found anywhere else.

Other kinds of repositories

A few of the other kinds of repositories are described below:

The Archives of Krishnamurti Foundation India (KFI), Chennai

The materials include

documents and records of Krishnamurti's life, books, manuscripts, transcripts, journals, letters, newspaper cuttings, organizational documents, photographs, audio tapes (including digital audio tapes), gramophone records, videotapes, films, and CD-Rom.^[78]

J. Krishnamurti was a great scholar and thinker.

Godrej Archives, Mumbai

It is a record of the contribution made by the Godrej Group to the "industrial history of India, as well as the country's future." Being company archives,

it houses an assortment of agreements, letters, technical drawings, press clippings, old catalogs, advertisements, testimonials from clients and customers, audio-visual recordings, photographs, awards, medals and unique memorabilia items.

The collection consists of manuscripts, photographs, audio-visual materials, memorabilia, printed materials and oral history records. The Manuscript Collection (1836–2007) includes old documents (553 accessioned files). Based on information provided by Ms. Vrunda Pathare, Godrej Archives, Godrej & Boyce Mfg. Co. Ltd., Mumbai. *The French Institute of Pondicherry, Pondicherry*

The major collection consists of 8187 palm-leaf bundles, 360 paper codices and 1144 recent paper transcripts (i.e., post-1950 paper manuscripts commissioned or copied by employees of the IFP), which are now on-line.^[79]

Mukul Dey Archives, Santiniketan

Mukul Dey was a pioneer Indian graphic artist, who has left behind a large body of work. The work throws light on the early twentieth century Indian art scene. This is a private archives. The entire body of the Archives consists of "anywhere between 500–750 individual files and more."^[80]

The Roja Muthiah Research Library, Chennai

The Roja Muthiah Research Library (RMRL), founded in 1994, provides research materials and facilities for students of Tamil studies.^[81]

Sarasvati Mahal Library, Thanjavur

The Thanjavur Maharaja Serfoji's Sarasvati Mahal Library is one gem among a few medieval libraries existing in the world. "It is an unparalleled repository of culture and an inexhaustible treasure house of knowledge built up by successive dynasties of Nayaks and the Marathas of Thanjavur."^[82] It is considered as a great treasure house of manuscripts, maps, paintings and books on art, literature and culture.

Tata Institute of Fundamental Research Archives, Mumbai

TIFR Archives, Mumbai, stores the collective memory of the institute by preserving records that tell the history of the Institute from 1945 to the present. The holdings include manuscripts, photographs, oral histories; print and audio-visual material; fine arts and scientific instruments as well as digitized recordings of lectures given by distinguished visitors to the Tata Institute Based on notes provided by Dr Indira Chowdhury, Consultant Archivist, TIFR Archives, Mumbai. Under one roof, researchers can find a rich resource for not only history of TIFR, but also for history of science in India.

The Tata Central Archives, Pune

The Tata Central Archives (TCA) is the first ISO 9001:2000 Certified Business Archives in India. They "collect, and retain letters, documents, images, printed books, group publications and ephemera of potential historical and critical significance to the Tata Group, one of the largest and most respected business houses in India."^[83]

Realizing the importance of archives, many other corporate groups also have set up their archives. These include Ambanis, Indian Aluminum Company and DCM group.

Digital archival collections and digital finding aids

There are many projects for digitization of archival collections that have been undertaken during the last few years. Some of these are described here.

Computerization and digitalization program at NAI, for an “Automated Retrieval System” has been undertaken and

computerization of reference media to records of the Home (Pub.) (1748–1859), Home (Pol.) (1907–1968), Foreign & Political Deptt. (1860–1946), Ministry of External Affairs (1947–1970) and Ministry of State (1947–1953) has been completed.

NAI has also computerized the reference media of Library Books. A Project for WAN Connectivity of five Libraries under Ministry of Culture is in progress. NAI has also undertaken a project with the assistance of the National Institute of Advanced Studies, Bangalore, for digitalization of rare and valuable manuscripts.^[84]

Under five-year plan (2007–2012), it has been proposed that

In order to minimize deterioration of rare and old records due to continuous handling, a new scheme of digitization of rare and old records may be implemented by NAI. . . Under the new proposed scheme for 11th Five Year Plan, NAI is to launch an archives of E-Records in collaboration with those Ministries where e-governance has made considerable head way.^[67]

The work is going on under this scheme.

The Indira Gandhi National Centre for the Arts (IGNCA), has created a digital library on Indian art and culture.^[85] The digital library of IGNCA is a tremendous effort and a valuable asset, covering a wide range of records.

Archival Science as a Discipline and Profession

Archival science in India has become a discipline in its own right. It has a growing body of knowledge. The theoretical issues are coming to the forefront. Archival science as a subject of study is being taught in India at the university/college/institute level.

Archivists are mostly employed by the National Archives and its branches, in state and local archival departments. However, increasingly, industrial and commercial firms, business houses, universities, religious institutions and libraries also have positions for archivists.

Education for Archivists and Records Managers

The NAI has been conducting training course in Archives Keeping since 1941. Archival education at the formal level can be traced to 1976, when the Institute of Archival Training was established at New Delhi. It was later, in 1980, renamed as the School of Archival Studies. Today, there are a number of universities and institutes that impart education for archivists and record managers.

The information about the courses offered is given in the next few paragraphs.

School of Archival Studies, National Archives of India, New Delhi

The School offers a one-year diploma course in Archives and Records Management. This School also offers certificate courses in Care and Conservation of Books, Manuscripts and Archives (8 weeks) and Reprography (4 weeks). Short-term certificate courses in Archives Management and Record Management and sub-professional courses in Servicing and Repair of Records are also being run by it.

Institutes/Universities offering post-graduate diploma, postgraduate certificate and undergraduate degree in archival studies include:

Post-graduate diploma courses

1. Diploma in Archival Studies (one-year)
School of Archival Studies, NAI
2. PG Diploma in Archives Keeping (part-time)
Annamalai University, Annamalai Nagar
3. PG Diploma in Archives and Documentation and Management
4. PG Diploma in Archival Science and Manuscriptology, Osmania University, Administrative Building, Hyderabad
5. PG Diploma in Archival Studies
Pondicherry University, Pondicherry
Postgraduate certificate courses
6. PG Certificate in Archives, Gujarat Vidyapith, Ahmedabad
Undergraduate courses
7. BA in Archival Science, Maharishi Dayanand Saraswati University, Ajmer—Eligibility: 10 + 2

According to Johare,

There is little evidence of concern for education and training of record keepers in managing electronic records in India. . . the curriculum content remains traditional in approach due to the lack of local expertise and facilities to deliver education and training programs on ERM.^[86]

In view of the significance of electronic records management (ERM), this area needs to be covered adequately in courses for education and training of record keepers.

There are no advance courses at the Master's level and there is also a need to start a Ph.D. program. Need exists for starting separate departments of archival science at universities.

Professional Associations

There are two major professional bodies in the country. These are The National Committee of Archivists and the Indian Historical Records Commission as described below:

The National Committee of Archivists

The National Committee of Archivists is a professional body of archivists from all the States and Union Territories. It has a purely advisory role.^[87]

The Indian Historical Records Commission

The Indian Historical Records Commission was set up by the Government of India in 1919 as a consulting body.^[88] The Commission has played a significant role in various matters relating to different aspects of archives. Its opinions carry a great deal of weight with different levels of the government.

Association of Indian Archivists, New Delhi

Association of Indian Archivists is a national association. Archivists and archival institutions are its members. The association is rather inactive and many archivists are not aware of its activities.

Electronic Records as Archival Documents

Under the 11th five-year plan (2007–2012), it has been proposed that “...NAI is to launch an archives of E-Records in collaboration with those Ministries where e-governance has made considerable head way.”^[67] ERM presents many challenges. One main challenge is to ensure that digital records remain sustainable, authentic and accessible over a period of time.

Preservation of Documents

Preservation of documents is a major issue. In recent years, the state has taken active steps in this direction. For the latest five-year plan (2007–2012), the Working Group of the Ministry of Culture,

also recommended implementation of a new scheme: ‘Assistance to the State Archives to Conserve and Digitize Records of National Importance.’ Under the scheme, identification of records of national importance held by the State Governments Archives will be undertaken so that these Archives could be assisted on a project mode to conserve and digitize the same.^[89]

A scheme of financial assistance to support Archival Repositories, Government Libraries/Museums of State/ Union Territory Administrations for their developmental activities and preservation of records, books and manuscripts, is available. The Department of Culture, Government of India has set up a Grants Committee under the above scheme for allotting grants in aid of preservation of records. The above scheme is being used by state archives,

libraries and other institutions for preservation/conservation/repair of the records.

NFAI is taking good care of its film collection.

In the beginning, the NFAI film collection was stored in improvised film vaults in the premises of the Film and TV Institute of India. Since the inauguration of its new building in 1994, NFAI has its own film vaults designed according to international film preservation standards.^[90]

Other Issues

Archival studies in India face a large number of issues.

Many records collections are still without any guides or hand-book let alone comprehensive descriptive lists, and very few repositories, public or private, have yet developed a well-articulated program of documents-publication. Most of the collections still continue to be housed in primitive conditions... Very little systematic effort has been made to survey, describe, organize or make use of records in private custody, and particularly, those of institutional, religious or commercial provenance. Lack of trained archivists continues seriously to impede the archival work in the country...^[88]

Similar issues have been raised by Rakesh Mohan. He has pointed out that “Establishing physical, administrative and intellectual control over our documentary heritage is the most challenging job because of sheer variety of media on which records are stored.”^[91]

Conclusion

Up to now, the field of archival studies in India has been a rather neglected one. In recent years, business houses such as Ambanis, TATA, DCM, Godrej, Indian Aluminum Company, etc. have set up their archives. In addition, a number of academic and research institutions have taken initiative to establish their archives.

Under the Eleventh Five-Year Plan (2007–12) of the Government of India, a number of schemes and projects are being implemented for collection of private papers, networking of state and national archives, digitization and preservation of records and modernization of archives. In view of these developments, the demand for trained archivists should increase. There is going to be an increasing potential for employment in this area.

MUSEUMS AND MUSEOLOGY

Introduction

History of museums

In India, precursors of the museum included prehistoric cave paintings, *alekhyagrihas* (*Ranga Mahal*—Hall of

paintings), *chitrasalas* (Paintings Gallery), *devakulas*, *visvakarma mandirs* and monasteries, that served the purpose of education and healthy entertainment. The great stupa at Bharhut with its inscriptions in the contemporary *Brahmi* for identification of schemes did exist as an open-air museum. Even today, temples, monasteries etc., function as museums in the country. The genesis of the present day museum goes back to the foundation of the Asiatic Society of Bengal in 1784. For the first time, the Asiatic Society of Bengal, by a historical decision in 1796 to open its collection to the public, established the Indian Museum, Calcutta in 1814. Six provincial museums were established in South India around that time. This period was a great incentive for other parts of the country to accelerate the museum movement slowly but steadily.

The outburst of Indian Mutiny in 1857 left its impact on the growth of the cultural institutions. By the year 1857, there were twelve museums in India. The progress of the Indian Museum Movement was slowed down for a short while. During the coronation year of Queen Victoria, 1887, many museums were established.

The dawn of the twentieth century was an era of awakening and great reforms. Because of the efforts of Lord Curzon many on-site museums were opened at important sites through the Archaeological Survey of India. During the visit of the Prince of Wales to India, in order to commemorate this occasion, the Prince of Wales Museum was opened. It was completed in 1914. In 1936, there were 105 museums of all sorts in India. In 1946, all the museums under the Archaeological Survey of India were brought under the control of the Museum Branch of the Archaeological Survey of India. In the middle of the twentieth century State Museum of Assam, Guwahati (1940), Central Museum, Arunachal Pradesh (1956), Punjab Government Museum (1959), Orissa State Museum (1963), and Manipur State Museum (1969) were established. As of 2008, there are about 700 museums in India.

In recent times, there has been a tremendous interest taken by national policy makers, scholars and cultural icons in museums. This has led to an extraordinary growth in museums of different kinds. During the last 10 years are so, major changes in the field of museology in India have taken place. Museums are using ICT (information and computer technology) in the display of museum objects, digitization of museum objects, dissemination of knowledge through the Web sites, publications, e-governance, ticketing, security, audio-guide, etc.

A National Mission on Monuments and Antiquities has been established. It has launched its activities throughout the country with independent functional strategy in each state and union territory. It is envisaged that the mandate of the Mission should be achieved within a stipulated time frame of 5 years i.e., 2007–2012. These are positive developments.

Legislation

The cultural renaissance of the early nineteenth century included enactment of the first ever-antiquarian legislation in India known as Bengal Regulation XIX of 1810. This was soon followed by another legislation called as Madras Regulation VII of 1817. Both these regulations vested the Government with a power to intervene whenever the public buildings were under threat of misuse. The Act XX of 1863, was therefore enacted to empower the Government to prevent injury to and preserve buildings remarkable for their antiquity or for their historical or architectural value.

The Indian Treasures Trove Act, 1878 (Act No. VI of 1878) was promulgated to protect and preserve treasures found accidentally but had the archeological and historical value. In a landmark development in 1886, James Burgess, the then Director General, succeeded in prevailing upon the Government for issuing these directions: forbidding any person or agency to undertake excavation without prior consent of the Archaeological Survey of India and debarring officers from disposing of antiquities found or acquired without the permission of the Government.

Cultural heritage ushered in a new era when The Ancient Monuments Preservation Act, 1904 (Act No. VII of 1904) was promulgated. This Act provided effective preservation and authority over monuments particularly those, which were under the custody of individual or private ownership. The next important act was The Antiquities Export Control Act, 1947 (Act No. XXXI of 1947).

When the Ancient and Historical Monuments and Archaeological Sites and Remains (Declaration of National Importance) Act, 1951 (No LXXI of 1951) was enacted, all the ancient and historical monuments and archaeological sites and remains protected earlier under “The Ancient Monuments Preservation Act, 1904” were re-declared as monuments and archaeological sites of national importance. Another 450 monuments and sites of Part ‘B’ States were also added. Some more monuments and archaeological sites were also declared as of national importance under Section 126 of the States Reorganization Act, 1956.

The Ancient Monuments and Archaeological Sites and Remains Act 1958 (No 24 of 1958) was enacted on August 28, 1958. This Act provides for the preservation of ancient and historical monuments and archeological sites and remains of national importance, for the regulation of archeological excavations, and for the protection of sculptures, carvings and other like objects. The Antiquities and Art Treasures Act 1972 (No. 52 of 1972) is the latest Act, enacted on September 9, 1972 for effective control over the moveable cultural property of antiquities and art treasures.^[92]

The Archaeological Survey of India (ASI), under the Ministry of Culture, is the premier organization for archaeological research and protection of the cultural heritage of the nation. Maintenance of ancient monuments

and archaeological sites and remains of national importance are the prime concerns of the ASI. Besides, it regulates all archaeological activities in the country under the Acts of 1958 and 1972. At present there are 41 site museums under the control of ASI.

National Museums

Indian Museum, Kolkata

This Museum is an autonomous institution of national importance, funded by the Department of Culture, Government of India. It was established on February 2, 1814 at the Asiatic Society, the earliest learned body in the country. It is considered one of the oldest regular museums of the world and repository of the largest number of museum objects in India.

National Museum, New Delhi

On August 15, 1949, C. Rajagopalachari, the then Governor General of India inaugurated an exhibition at the Audience Hall of the Rashtrapati Bhavan that later formed the nucleus of the National Museum. The exhibition at the Audience Hall consisted of items which had been sent to the Royal Academy, London for an exhibition earlier in 1949. The objects received from various museums for the purpose of the exhibition were not returned to the respective museums. Instead it was decided to keep the objects in New Delhi to form the National Museum. The National Museum, New Delhi, started functioning in a true sense only with the inauguration of the first unit of its building on December 18, 1960. Apart from collections of Pre-history, Archaeology, Jewellery, Paintings, Decorative Arts, Manuscripts, Central Asian Antiquities, Anthropology, Pre-Columbian and Western Art, Arms and Armour and Numismatics and Epigraphy, the museum today has separate branches of Publications, Public Relations, Education, Library, Exhibition, Display, Modeling, Photography, Security and Administration. A well-equipped Conservation Laboratory not only provides restoration to all the art objects but also training facilities to the students and deserving professionals. There are galleries for Pre-history, Indus Valley Civilization, Maurya, Satavahana and Sunga Art, Late Medieval Art, Indian Bronzes, Central Asian Art, Chamba Rangmahal, Indian Miniature Paintings, Manuscripts, Pre-Columbian and Western Art, Indian Coins and Copper Plates, Arms and Armour, Wood-carvings and Musical Instruments. New galleries include Buddhist Art, Tantra Art, Evolution of Indian Scripts and Coins, Decorative Arts, Paintings from Tanjore and Mysore, Tribal Life Style of North-East India, Jewellery, Indian Textiles have been set up recently. An exhibition of India's maritime heritage set up by the Indian Navy in the National Museum covers the evolution of maritime activity of India.

National Museum of Natural History, New Delhi

In 1972, it was decided that the country needed a museum of Natural History to depict its flora, fauna and mineral wealth, to provide an out of school facility for education of children and to promote environmental awareness among the masses. The museum opened its doors to the public on June 5, 1978, with a gallery on Natural History. Since then it has added three galleries, a Discovery and Activity Room for pre-school children. It has also conducted a variety of educational programs and brought out popular literature. In addition, the museum started three regional centers at Mysore, Bhopal and Bhubaneswar. The museum has four exhibit galleries, namely: The Introduction of Natural History, Nature's Network Ecology, Conservation and Cell—The Basic Unit of Life. These not only provide useful information to the visitors but also serve as valuable resources in supplementing classroom teaching.

National Children's Museum, New Delhi

The National Children's Museum displays a rich collection of toys and dolls from different countries, stone and bronze objects, traditional jewelry, arts and crafts, musical instruments, currency of various countries, etc. The Children's Creative Work Gallery, displays the pieces of arts created by children. Summer camps are organized, with workshops on arts, theatre, painting, music, dance, etc. The Museum also provides drama kits, stories, puppets, toys, costumes and puppet shows. The museum complex includes a hostel, sports facilities, science park, aquarium, jet fighter, functional mini train, etc.

National Rail Museum, New Delhi

The National Rail Museum is a museum in Chanakyapuri, New Delhi which focuses on the rail heritage of India. It opened on the February 1, 1977. It is located in over 10 acres of land with both indoor and outdoor exhibits. A toy train offers rides around its site on regular days. The Museum houses the world's oldest operational steam locomotive (certified by the Guinness Book of Records), the Fairy Queen, built in 1855.

National Gandhi Museum, Delhi

The National Gandhi Museum, Rajghat, has an extremely impressive collection of books, journals and documents, audio-visual materials, exhibits, photographs, relics, memorabilia and art pieces that are related to Mahatma Gandhi, Father of the Nation (India). This museum was opened in the year 1961. It is an excellent place for researchers and students interested in Gandhian thoughts and the Indian Freedom Struggle.

The Allahabad Museum, Allahabad

The Allahabad Museum, Allahabad, was declared as an institution of national importance by the Government of India in 1985. This Museum is famous for its collection of Bharhut, Bhumara and Jamsot, Sculptures and for the terracotta from Kausambi, Bhita, Jhusi, Patliputra, Sarnath, Rajghat and Ahichhatra. The Museum also has paraphernalia and heirlooms of the Nehru family, including manuscripts of *An Autobiography* by Jawaharlal Nehru and a large volume of correspondence. Among the Museum collections are paintings by members of the Bengal School of Painters and Vijayavargiya. Among the foreign painters, mention may be made of Nicholas Roerich, his son Svetoslav Roerich and Anagarika Govinda.^[93]

The National Gallery of Modern Art, New Delhi

The National Gallery of Modern Art was inaugurated on March 29, 1954. The Gallery is the premier institution of its kind in India. The NGMA has two branches at Mumbai and Bangalore. The gallery is a repository of the cultural ethos of the country and showcases the changing art forms in the field of Visual and Plastic arts, starting from about 1857.

National Gallery of Portraits, Chandigarh

The visuals and documents which are displayed in the gallery tell the story of how the people of India waged a struggle to win back their freedom and to build a new India. These give a glimpse of the reawakening of India from the time of first war of independence of 1857 to the achievement of freedom in 1947. The gallery displays forty- one well researched computer generated photo and document panels. The panels are supported by the oil paintings of portraits, metal and plaster cast sculptures of selected freedom fighters, murals and dioramas.

The Government Museum and Art Gallery, Chandigarh

The Government Museum and Art Gallery, Chandigarh is an art gallery. Established in August 1947, the building is square (165 feet by 165 feet) and was designed by Le Corbusier (Charles-Édouard Jeanneret-Gris).

Other than the gallery itself, it has the following sections:

- The National History Museum
- The National Gallery of Portraits
- The Chandigarh Architecture Museum

The museum/art gallery exhibits 10,000 mostly Indian artwork such as sculptures and paintings. The attached reference library houses approximately 10,000 media.

National Philatelic Museum, New Delhi

The Museum is located in the Dak Bhavan which has a post office with a popular outlet for the philatelists interested in Indian stamps. The National Philatelic Museum has an elaborate collection of stamps both of the pre- and the post-independence periods. The museum depicts the story of Indian Philatelic Heritage and also the stamps issued by the Indian government. The postal history of India is displayed in the museum, which serves to be an education for visitors. The stamps, which were cancelled, are also displayed in the National Philatelic Museum, New Delhi. The sales counter of the museum sells stamps from all over the world.

National Science Centre, New Delhi

This Centre houses a unique collection of science models to arouse interest among children. The children are made aware of the effective use of science in our lives. It is one of the best science centers of the National Council of Science Museum (NCSM) exhibiting scientific models and intriguing artifacts. Several galleries in the centre pertaining to various themes have a plethora of exhibits. These exhibits are based on different laws and theories of science.

Strengthening and Modernization of Museums

Emphasis has been given for Modernization of Museums in four metropolitan areas, namely Delhi, Kolkata, Mumbai and Chennai during the 11th five year plan (2007–2012). Accordingly, a new scheme for “Modernization of Museums in Metro Cities” will be taken up for its implementation during the Eleventh Plan. As such, technological up-grades of various important museums/galleries such as the National Museum, National Gallery of Modern Art, Salar Jung Museum and Indian Museum are being taken up.

The existing Scheme of Promotion and Strengthening of Regional and Local Museums also has been revised to make those museums effective and much more relevant. In order to develop the Gandhi Darshan at Rajghat, Gandhi Smriti and Darshan Samiti (GSDS) will take up the development work of the complex to make it into a tourist destination and a Center of Excellence.^[94]

Major Art Museums and Galleries (Noncommercial)

Chhatrapati Shivaji Maharaj Museum (Prince of Wales Museum), Mumbai

The Museum was opened to the public on January 10th, 1922. The collection of the museum includes the

collections of Sir Purushottam Mavji (1915), the gift of Sir Ratan Tata (1921), the collection of Sir Dorab Tata (1933) and the collection of sculptures and coins from the Poona Museum and Bombay Branch of Royal Asiatic Society. There are terracotta objects of the Indus Valley civilization, Buddhist sculptures like Bodhisathva, Maithreya, Uma Maheswara panel, a panel of Brahma, Vishnu on the Sessa, clay and stone tablets, personal emblems of traders, jewellery, paintings, thankas, Bidri work, decorative art works, glass, jade, porcelain wares, mammals, birds, and fishes are the important collections of the museum.

Goa State Museum, Goa

The Goa State Museum is known as much for its impressive architecture as for the splendid collection of ancient artifacts and sculptures. It houses an eclectic collection of over 8000 items including stone sculptures, wooden objects, bronzes, paintings, manuscripts, numismatic collection, and anthropological objects.

Government Central Museum, Jaipur

Government Central Museum not only houses many rarities and beautiful objects but its own building is also a sight to behold. The upper floor/level of the Museum mainly has portraits of royalty and Jaipur Maharajas. It has an extensive collection of jewelry, metalwork and sculpture. There are also many objects made of brass, which display the skills of the expert hands that have hammered and chiseled them to perfection. The Museum also has a huge collection of miniature paintings from the Udaipur, Jaipur, Bundi, Kota, and Kishangarh schools of painting. There are also fine specimens of woodwork, metal objects and other arts & crafts.

Government Museum, Chennai

The Madras Museum was organized during the year 1851, with about 1100 geological specimens. Museum doors were thrown open to the public on April 29, 1851. In 1896, the Front Building with the Museum Theatre and The Connemara Library was built. In 1909, Victoria Memorial, the present National Art Gallery Building, was constructed. In 1939, the New Extension Building, i.e., the main entrance building was opened. In 1963, the buildings for the Bronze Gallery, Birds' Gallery and the Chemical Conservation and Research Laboratory were added to the museum. The Contemporary Art Gallery and the Children's Museum were added to the museum in 1984 and 1988 respectively.

This museum is the oldest museum in the country, having its own conservation laboratory. The laboratory of the museum was established in 1930. In the beginning it was catering to the needs of the Madras Museum, especially to preserve the bronzes and metallic objects. Now it

is meeting the conservation needs of the Central museum and the 15 district museums. Training programs are conducted for the museologists, archivists, executive officers of the Hindu Religious and Charitable Endowments Department and others.

International Dolls Museum, Chandigarh

International Dolls Museum in Chandigarh, established in 1985, is one of the best museums of India. It houses splendid dolls and puppets gathered from all over the world. It has about 250 different kinds of dolls collected from countries like Denmark, Germany, the Netherlands, Spain, Russia, Korea, etc. An added attraction for children is the toy train.

Salar Jung Museum, Hyderabad

Salar Jung Museum, Hyderabad, has a great history behind its formation. Its collection grew out of the rich and variegated collection made by the family of Salar Jungs. In 1961, through an Act of the Parliament, the museum, along with its Library, was declared as a Museum of National Importance. Salar Jung Museum has a total collection of 48,361 items. These objects are being classified into Indian, Western, Middle Eastern and Far Eastern collections. It is a very popular museum.

Thanjavur Art Gallery, Thanjavur

The Art Gallery at Thanjavur is housed in the former palace of the Nayaks, who were once the viceroys of the Vijayanagara rulers and later became rulers themselves. The gallery houses a treasured collection of bronze icons, stone sculptures and other artifacts. The examples of art that we see today at this gallery are the finest of their kind. Most of the pieces belong to the Chola period between the ninth and the thirteenth centuries A.D., to the post-Chola period and to the Nayak period, from the seventeenth to the eighteenth Century A.D. The gallery also houses a few sculptures from the Pallava period.

India's First Sex Museum (Antarang), Mumbai

The clinic-cum-museum, Antarang, was the brainchild of Grant Medical College alumnus and artist Dr. Prakash Sarang. City authorities in Mumbai in 2002 opened a sex museum to raise understanding about sex and related issues. This is the city's—and probably India's—first such museum.^[95]

Science and Natural History Museums

Science museums

From the early days of its independence (1947), an emphasis was placed on research in science and technology that

transformed India into an important industrial and technological power in the twenty-first century. Science museums have played an important role in creating a social awareness about scientific progress made by the country. Some of the leading science museums are described in the next few paragraphs.

Birla Industrial and Technological Museum, Kolkata. Birla Industrial and Technological Museum was established in 1956, by the Council of Scientific and Industrial Research. Since 1978, the museum has come under the National Council of Science Museums (NCSM). The primary objective of the museum is to arouse scientific curiosity and an understanding of science and technology among the common people, especially the student-community.

It has a large number of exhibits. Galleries cover models showing Electricity, Nuclear Physics, Iron and Steel, Optics, Motive Power, Communication and Mining. The Optics Gallery has since been converted into a Popular Science Gallery. Popular activities of the Museum include films shows, demonstration-lectures, hobby activities, and periodical programs of sky-observation through telescopes. The museum also has a small “animalorium” with live snakes, reptiles, rabbits, an aviary and aquariums. An Underground Mock-up Coal Mine, Rabbit House, Snake Pits, Aquarium, Aviary, Bonsai and Cacti Garden are some of the other attractions.

Nehru Science Centre, Mumbai. Nehru Science Centre uses innovative ways to communicate science in ways that enthuse, entertain, initiate, excite and to enhance public understanding of science and spread scientific literacy. The galleries in the main building are full of exciting, interactive and interesting exhibits on topics quite relevant to school curriculum and general interest in science. These exhibits also facilitate people in general to understand and appreciate principles of science through fun and pleasure.

The National Science Centre, Delhi. The National Science Centre, Delhi, was inaugurated on the January 9, 1992, is a pioneering institute engaged in the organization of science among the people of the northern part of India in general and among students in particular. Since opening, the Centre has rendered yeoman service to the cause of science organizations.

Periyar Science and Technology Centre, Chennai. The Periyar Science and Technology Centre was established in 1986. It is a Science and Technology Museum run by the Government of Tamil Nadu. This thrust of the museum is to popularize science and technology among students, the general public and tourists. This museum has seven galleries popularizing scientific and technological aspects through working models. Most of the exhibits are

interactive. It also has a Science Park, Eco Park, Energy Park, Traffic Park and a model meteorological observatory.

The Regional Science Centre, Bhopal. The Regional Science Centre, Bhopal was opened on January 12, 1995. Umbrella—The Atmosphere, Fun Science, Life Science, 3D Science Show Theatre, Children’s Activity Corner, Science Park are some of the important galleries of the Centre. The Fun Science Gallery of the Centre offers learning through play.

The Regional Science Centre, Lucknow. The Regional Science Centre has been functioning since 1989 as a centre of interactive science learning. The upgrade of the Centre to the Regional Science City was effected on September 21, 2007. The objective of the upgrade is to create scientific awareness and temperaments among students and the public, and to supplement formal science education and create interest in science among students. Some of the attractions include underwater Exploration, Biotechnological Revolution and Being Human, 3-D Science Show and Space Theatre where Large Format Film Projection.^[96]

Science City, Kolkata. The Science City, Kolkata, was built recently, in the twenty-first century. The concept of science city is simply mind-blowing. There are cable cars, a toy train and a children’s playground with jungle gyms and slides. Dynamotion is a great favorite among children, with its large exhibit on physics and mechanics. Life-size dinosaurs, aquariums, insectariums and the butterfly corner are also great attractions. Science City also has a Time Machine, which simulates a journey into the past and future with sights and sounds. The Space Theatre is by far the most popular attraction.

Visvesvaraya Industrial and Technological Museum, Bangalore. The museum opened to the public in 1965, has seven permanent exhibition halls viz. Engine Hall, Electro-technic, Fun Science, Space-Emerging Technology in the service of mankind, Biotechnological Revolution, BEL-Hall of Electronics, Science for Children and two special exhibits viz. Dinosaur Corner and Wright Brothers’ Aero- plane.

Natural history museums

The Natural History Museum, Chandigarh. In 2001, the existing museum of Evolution of Life was upgraded to its present status as the Natural History Museum with five major sections:

- Cyclorama of Evolution of Life
- Nature in Art section
- Manuscript section

- Evolution of Man section
- Dinosaurs of India section

The Nehru Planetarium, New Delhi. The Nehru Planetarium in New Delhi is situated in the sprawling surroundings of the Teen Murti House. In 1964, the Jawaharlal Nehru Memorial Fund was set up to promote ideas of Jawaharlal Nehru and subsequently it undertook to build the Nehru Planetarium. The primary aim of the Planetarium is the promotion of astronomy and space education.

Historical, Anthropological, and Archaeological Museums

Nehru Memorial Museum and Library, New Delhi

This museum revolves around the life and works of Jawaharlal Nehru (former Prime Minister), especially those objects pertaining to the freedom struggle. A collection of photographs and newspapers enables one to have a feel of the stirring events that led to the birth of the Indian Republic. The Museum has a library also which is a storehouse of books on Indian history and Indian national movement.

Birla House, New Delhi

The Gandhi Smriti or Birla House or Birla Bhavan, in New Delhi, is the location where Mahatma Gandhi (the Father of the Nation) spent the last 144 days of his life and was assassinated on January 30, 1948. It was originally the house of the Indian business tycoons, the Birlas. It was acquired by the Government of India in 1971 and opened for the public on August 15, 1973 and renamed the Gandhi Smriti (or *Gandhi Remembrance*). The museum in the building houses a number of articles associated with Gandhi's life and death. Visitors can view the preserved room where Gandhi lived and also visit the place on the grounds where he was shot while holding his nightly public walk. The Martyr's Column now marks the place where Gandhi, the "Father of the Nation" was assassinated.

Anthropological Museum (Department of Anthropology, University of Delhi), Delhi

The Museum consists of

a large number of material cultural objects associated with different economic and social types, such as hunting and food-gathering, fishing, horticulture, animal breeding, farming and agriculture. Musical instruments from different societies are also kept in the Museum. So are the models of different types of habitation from Indian tribes. Dresses and ornaments, and weapons, constitute a separate section in the Museum.

The museum has a

rich collection of stone and bone implements ...The Museum also had a handsome collection of the casts of fossil man. Stuffed great apes are also kept, so are the bones of the nonhuman primates. All these are used for physical anthropological work.^[97]

The Museum is considered one of the best anthropological museums in the country.

The Archaeological Museum, Khajuraho (Madhya Pradesh)

It was established in 1904 and has excellent exhibits of sculptures from the temples of Khajuraho.

Sarnath Archaeological Museum

Amongst the exhibits at the museum are the figures and sculptures that date back to the Mauryan, Kushan and Gupta period of Sarnath. While holidaying in Sarnath one should not miss the Asokan Pillar, the prime attraction of the archaeological museum.

The Archaeological Museum, Nalanda

The Archaeological Museum at Nalanda in Bihar is a storehouse of the excavations from Nalanda and Rajgir. The exhibits at the museum include sculptures and various other archaeological remains.

The Archaeological Museum, Delhi

The Archaeological Museum of Delhi is situated in the Mumtaz Mahal (Palace) of the Red Fort. The museum has on display some of the rare relics dating back to the Mughal era, along with specimens of the fine calligraphy of the past. The main reason to establish the museum was to bring together all the items reminiscent of the history of the city of Delhi under one roof. The Museum includes excavated objects belonging to the Maurya, Sunga, Kushana, Rajput, and the Muslim period.^[98]

Surveys of India

There are various Surveys in India that take stock of the situations in respective disciplines such as anthropology, archaeology, botany, geology and zoology. These Surveys are under the control of the Government of India. They are closely connected with museums and museology.

The Archaeological Survey of India (ASI), under the Ministry of Culture, is the premier organization for archaeological research and protection of the cultural heritage of the nation.

The Anthropological Survey of India (AnSI) is a unique organization dealing with the anthropological research in public or private sector and regulates the anthropological activities such as studying tribes and other communities.

The Botanical Survey of India (BSI) is an institution under the supervision of the Union Ministry of Environment and Forests that surveys the plant resources of the Indian empire.

The Geological Survey of India (GSI), one of the oldest surveys in the world, is a premier organization of Earth Science Studies in the sub-continent. The Zoological Survey of India (ZSI), as the premier national organization under the Government of India engaged in field survey and laboratory investigation on faunal resources of India.

Zoos

There are 169 recognized zoos in the country. Leading zoos are described below:

The Alipore Zoological Gardens, Kolkata

The Alipore Zoological Gardens (also informally called the Alipore Zoo, Calcutta Zoo or Kolkata Zoo) is India's oldest formally stated zoological park (as opposed to royal and British menageries) and a big tourist attraction in Kolkata. It is home to one of the few captive breeding projects involving the Manipur Brown-antlered Deer.

Arignar Anna Zoological Park, Chennai

Chennai has the distinction of having the first zoo in India, which was started in 1855. It has a Lion safari, Bird aviaries, Reptile House, Nocturnal House, and Mountain Cave Entrance.

Indira Gandhi Zoological Park, Visakhapatnam

Indira Gandhi Zoological Park is located amidst Kambalakonda Reserve Forest in Visakhapatnam. Nearly 80 species numbering about 800 animals are found in the zoo. The Zoo Park has different sections for primates, carnivores, lesser carnivores, small mammals, reptiles, ungulates and birds caged in their natural ambiance.

Madras Crocodile Bank Trust

The Madras Crocodile Bank Trust or CrocBank is a reptile zoo and herpetology research station, located near Mahabalipuram, 40 km south of the city of Chennai. It was established in 1976 with the aim of saving the three Indian species of crocodiles—the marsh or mugger crocodile, the saltwater crocodile, and the gharial—which at the time were all nearing extinction. The captive breeding program of CrocBank has been highly successful, with

thousands of crocodiles reintroduced to the wild and more still sent to zoos and wildlife parks around the world. The CrocBank is currently home to over 2400 crocodiles, and also houses many species of turtles, snakes, and lizards which are viewable by the public.

Mysore Zoo, Mysore

The Mysore Zoo was established under royal patronage in 1892, making it one of the oldest zoos in the world. It is home to a wide range of wild species. The official name for the zoo is Shri Chamarajendra Zoological Gardens, though it is known commonly by its shortened name. Mysore Zoo is one of the city's most popular attractions.

Nandan Kanan Zoological Park, Bhubaneswar

The zoo was established in 1960–1961. A major renovation was done during 2000. Nandan Kanan is famous for its white tiger population, the species it claims to have produced. Endangered species such as the Asiatic lion, three Indian crocodilians, Sangal lion-tailed macaque, Nilgiri langur, Indian pangolin, mouse deer and countless birds, reptiles and fish have been breeding successfully at Nandan Kanan. Some of the other attractions of Nandan Kanan are the 34 aquaria which are home to a large variety of fresh water fishes. Around 67 kinds of mammals, 18 varieties of reptiles, 81 species of birds, and overall more than 1200 (as of 2005–2006) wild animals coexist in the deep forest. The zoo enjoys a good reputation, internationally, for successfully breeding black panthers, gharial crocodiles and white tigers in captivity. This is one of the few zoos in India where one can see animals in their natural environments.

National Zoological Park, New Delhi

The Delhi National Zoological Park is among the finest Zoological Gardens in the country. It has 2,000 varieties of animals and birds. The animals include Gir Lions, Zebras, Spider Monkeys, and Chimpanzees as well as innumerable reptiles and birds. There are also about 200 varieties of trees in the Park.

Nehru Zoological Park, Hyderabad

Nehru Zoological Park is the largest zoo in India. It was established in 1963. It has a wide selection of nearly 1500 species of birds, animals and reptiles housed here. The zoo runs different safari trips, like Lion Safari, Tiger Safari, Bear Safari, and Butterfly Safari. Other attractions include elephant rides, a Natural History Museum, and a children's train.

Padmaja Naidu Himalayan Zoological Park, Darjeeling

This Zoological Park specializes in breeding animals adapted to alpine conditions, and has done successfully captive breeding of the snow leopard, the critically endangered Himalayan wolf and red panda. The zoo now contains endangered animals like snow leopards, red pandas, gorals (mountain goat), Siberian tigers and a variety of endangered birds.

Parassinkkadavu Snake Park, Kannur, Kerala

There are about 150 varieties of snakes including the spectacled cobra, King cobra, Russell's Viper, Krait, and Pit Viper living in the park. The park also has a large collection of nonpoisonous snakes, including pythons.

Sakkarbaug Zoological Garden, Junagadh

Sakkarbaug Zoological Garden is also known as Sakkarbaug Zoo or Junagadh Zoo. It is famous worldwide for providing purebred Asiatic Lions for the Indian and the international endangered species captive breeding program for critically endangered Asiatic Lions. Wild free ranging Asiatic Lions have become extinct all over Asia and are today found only in the nearby Gir Forest.

Trivandrum Zoo, Thiruvananthapuram

This is one of the best designed zoos in Asia. It is also one of the oldest in the country, established as an annexe to the Museum (Napier Museum) in 1857 by the erstwhile Maharaja of Travancore. The Zoo has 75 different species of animals, not only from India but also from abroad.

Taraporewala Aquarium, Mumbai

Here one can view beautiful marine life, such as rare species of fish, and wonderful pearl jewelry.

National Parks

Indian National Parks provide many opportunities to the visitors to have a close encounter with the wild. But what is so fascinating about the Indian National Parks is that they have a great deal of variety. Seeing the flora, avifauna, and aquafauna, or witnessing various wild forms in their natural surroundings on an elephant or inside a jeep, or through wild ventures is a great experience not to be missed.

Some of the best jewels of Indian wilderness include the Great Himalayan National Park, Dachigam National Park near Srinagar, Corbett National Park in Uttar Pradesh (also a famous tiger reserve), Ranthambore National Park

in Rajasthan, and Sundarbans National Park in West Bengal. Worth visiting in the East Indian part of the country, in "The Land of Rhino" Assam, is Kaziranga.^[99]

Great Himalayan National Park (GHNP)

This national park, built in the year 1984, is located in Kullu region in the state of Himachal Pradesh. It is home to more than 375 faunal species. So far, 31 mammals, 181 birds, 3 reptiles, 9 amphibians, 11 annelids, 17 mollusks and 127 insects have been identified. A trek of 35–45 km. takes one to the high altitude habitat (3500 m and above) of various animals such as blue sheep, snow leopard, Himalayan brown bear, Himalayan tahr, and musk deer.^[100]

Dachigam National Park

Dachigam National Park is located 22 km from Srinagar, Jammu and Kashmir. The park has been a protected area since 1910. It was declared a National Park in the year 1981. The main animal species that Dachigam is most famous for is the Hangul, or the Kashmir stag. Other species that inhabit its interiors include musk deer, leopards, Himalayan gray langurs, leopard cats, Himalayan black bear, Himalayan brown bear, jackals, hill fox, Himalayan weasel, yellow-throated martens, jungle cats, long-tailed marmots and otters.^[101]

Corbett National Park, Ramnagar

This is the oldest national park in India. The park was established in 1936 as Hailey National Park. Located in Ramnagar, Nainital district of Uttarakhand State, the park is a protected area for the critically endangered Bengal tiger of India under the Project Tiger, an Indian wildlife protection initiative.

Ranthambore National Park

Ranthambore National Park is one of the largest and most famous national parks in India. It is situated in Sawai Madhopur district of Rajasthan, about 130 km from Jaipur. This Park was established as the Sawai Madhopur Game Sanctuary in 1955 by the Government of India. It was declared one of the Project Tiger reserves in 1973. Ranthambore became a national park in 1980. In 1984, the adjacent forests were declared the Sawai Man Singh Sanctuary and Keladevi Sanctuary. In 1991, the tiger reserve was enlarged to include both Sawai Man Singh and Keladevi sanctuaries as well. The park is famous for its tiger population. The major wild animals include the tiger, leopard, nilgai, dhole, wild pig, sambar and chital. It also has a wide variety of trees, plants, birds and reptiles. Ranthambore has one of the largest Banyan trees in India.

Sundarbans National Park

Sundarbans National Park (since 1984) is a Tiger Reserve, UNESCO World Heritage Site (since 1987) and a Biosphere Reserve (since 1989). It is located in the Sundarbans delta in West Bengal, lying in a region that is densely covered by mangrove forests. It is considered one of the largest reserves of the Bengal tiger. The park has a large variety of bird, reptile and invertebrate species, as well as salt-water crocodiles.

Kaziranga National Park

Kaziranga National Park is in the Golaghat and Nagaon districts of Assam. It was established in 1905 as a reserve forest. It is both a national park and World Heritage Site. Two-thirds of the Great One-horned Rhinoceroses of the world live in the park. Kaziranga has the highest density of tigers among protected areas in the world. It was declared a Tiger Reserve in the year 2006. The park has also a large population of elephants, water buffalo and swamp deer. Kaziranga is recognized as an Important Bird Area for the conservation of avifaunal species.

Digital Museum Exhibits and Services

Indian museums have been lagging behind in creating digital museums. However, there are signs that they are getting involved in this seriously. Some of the examples of museums that have ventured into this field are given below:

The Government Museum and Art Gallery, Chandigarh

A few years back, the Museum established the “Data Collection Management” section. Inputting of inventory data, object description and conservation data of the collection was started with a pilot project of 627 pieces of Gandharan sculptures. Inputting data about Indian miniatures, contemporary paintings, Indian Medieval and contemporary sculptures is also in progress.

Digital Library of India (Program)

The mission is to create a portal for the Digital Library of India (DLI) which will foster creativity and free access to all human knowledge. This portal will also become an aggregator of all the knowledge and digital contents created by other digital library initiatives in India. The Digital Library of India is mirrored at several locations so as to protect the integrity and availability of the data. The DLI is also a partner with other country specific Digital

Libraries initiatives as part of the Universal Library Project (<http://www.ulib.org>) spearheaded by Prof. Raj Reddy and Carnegie Mellon University.

Indian National Museum, New Delhi

Computerization and digitization for an automated retrieval system for the Museum has been completed. Computerization of reference media for certain records (such as records for the Ministry of External Affairs (1947–1970), Ministry of State (1947–1953), etc.) has also been completed. A project for digitization of rare and valuable manuscripts is ongoing.

The Indira Gandhi National Centre for the Arts (IGNCA), New Delhi

The National Mission for Manuscripts is one of the departments of IGNCA, created in February 2003 with an aim to protect the manuscripts culture of this country and it is also to carry out the digitization of the manuscripts.

Museology as a Discipline and Profession

Museology has come of age. Today, it has become a multi-disciplinary and increasingly interdisciplinary area of studies. At one time it was a minor area of studies, but now it has become a subject forming part of the mainstream.

Museology in India has grown into a profession in its own right. Museum scholars belong to different disciplines and backgrounds, bringing together a broad range of perspectives. Museology fulfills the characteristics of a profession. In recent years, there has been recognition of the need for trained professionals. Today, museum professionals are expected to possess professional qualifications obtained from recognized institutions.

Education for Curatorship and Museum Administration

Due to the recognition of need for professional training, a number of university level courses have been started.

The National Museum Institute of History of Art, Conservation and Museology came into existence in 1983 and now is deemed to be a University. It provides various Courses with its campus at National Museum (New Delhi).

Some of the Universities offering courses are:

Aligarh Muslim University, Aligarh

M.A. Program besides one-year diploma in museology and Ph.D. Programs

Banaras Hindu University, Varanasi

Diploma in Museology, M.A. in Museology after graduation and Ph.D
 Jiwaji University, Gwalior
 M.A. in Ancient History, Culture and Archaeology
 M.A. (Museology)
 PG Diploma in Archaeology
 Maharaja Sayajirao University, Baroda
 M.A. (Fine) Museology and Ph.D. Courses as well as 1 year Diploma Course for in-service people.
 National Museum Institute of History of Arts and Conservation and Museology, New Delhi
 M.A. (Arts History), M.A. (Conservation), M.A. (Museology); Ph. D (Art History), Ph.D (Conservation), Ph.D (Museology). Besides, the Institute also runs short-term courses in the History of Art stream for general public. The courses are:

- Art Appreciation Course (English)
- India Art and Culture Course (English)
- Bhartiya Kala Nidhi (Hindi)

University of Calcutta, Kolkata
 Diploma in Museology after graduation, M.A. in Museology, PG diploma in Museology and Ph.D. in museology.
 Vikram University, Ujjain
 1-year PG Diploma in Museology

Besides these many museums also provide training in museology and related subjects.

Chemical Conservation and Research Laboratory, Government Museum, Chennai, started a refresher course in 1974 on Care of Museum Objects. At present, it offers one-month long training in Care of Museum Objects for those who are working in museums in allied departments; Course on Care of Temple Antiquities for the Executive Officers of the Hindu Religious and Charitable Endowments Department, Government of Tamil Nadu, Chennai, a course on Care of Archival Materials exclusively for the Archivists, a Course on Care of Library Materials for Librarians etc.^[102]

The Conservation Laboratory of the National Museum, New Delhi organizes training programs for students, curators and conservators and also provides training facilities to students and professionals, including restoration of oil paintings. It organizes workshops and seminars at various places from time to time on conserving the vast cultural heritage of the country.

INTACH, Indian Conservation Institute offers various courses in Conservation of Paintings, Documents, and Manuscripts to graduates in Science or Chemistry graduates or BFA degrees at New Delhi and Lucknow.

Professional Associations for Curators and Museum Administrators

The following are the major professional associations:

Indian Council of Historical Research, New Delhi

The Indian council of Historical Research, New Delhi is an autonomous body established by the Government of India with a view to providing funds for historical research and to fostering objective and scientific writing of history. The Council has taken a broad view of history so as to include in its fold archaeology, socio-economic formations and allied subjects.

National Council for Science Museums, Kolkata

The National council of Science Museums, an autonomous organization under the Department of Culture, was set up in 1978 and is primarily engaged in the task of popularization of science and technology among the students in particular and the masses in general through a wide range of interactive programs and activities. It administers 21 science museums/centers/parks throughout the country.

Museum Association of India (MAI), New Delhi, c/o National Museum, New Delhi

The Museum Association of India was founded in 1944. The aim of the Association is to further the cause of museums in India by making them popular with the public by providing new ideas through seminars and publications, and by promoting mutual appreciation of mutual problems by holding museum conferences. The Association has also taken up the responsibility for representing the cause of museums and their personnel. The Museum Association of India brings out the *Journal of Indian Museums* and *Museum's Newsletter*.

Indian Association for the Study of Conservation of Cultural Property in India (IASC) c/o National Museum Institute, Janpath, New Delhi—110011

The Indian Association for the Study of Conservation of Cultural Property was started in New Delhi to create a common platform for conservation scientists, conservation chemists, conservators, architectural conservation engineers etc. It provides a professional centre devoted to the cause of conservation and study of cultural property including historic, archaeological, ethnological, artistic, archival and other material in libraries, manuscript repositories and museums. It brings out a journal called *Conservation of Cultural Property India* annually and *Conservation Newsletter* in August every year. Besides these, it also publishes books on special topics.

Indian National Trust for Art and Cultural Heritage (INTACH) Indian Conservation Institute

The main aims and objectives are: To take up conservation and restoration of different types of objects, to impart

training in different branches of conservation and to create awareness among the public about the need for conservation and the problems involved through periodical exhibitions, seminars and workshops.

The Indian Conservation Institute has branches at Bangalore, Bhubaneswar, New Delhi, Rampur, Jaipur, Trissur, etc.

Key Contemporary Issues

Publicity

An on-going study by the National Museum Institute has revealed that “about 90 percent of the people standing at the bus stop right outside the museum did not know where the museum was or what was in it?”^[103] This may be true to a large extent, even today. This shows lack of publicity.

Procurement

A large number of rare items of Indian origin are held by museums and private individuals in Europe and in South-east Asian countries. From time to time they appear at auctions. Indian museums sometimes have tried to acquire them, but due to lack of sufficient budget, they have not been able to acquire many pieces.

Preservation

The contemporary scene in India is abysmal and needs to be redressed for any meaningful discussion on plunder of the heritage. Although the ASI has declared over 3000 monuments as nationally important, it is the sixteen sites that have been declared as part of World Heritage that receive greater attention. Thus there is clearly an imbalance in regional coverage both of heritage sites and protected monuments. Similarly there are far more museums in cities than in rural areas, though even within the cities the situation is far from satisfactory.^[104]

Access

The social service role of Museums and Art Galleries in making their resources accessible to all is an important issue. There is a need for a National Policy on Museum Accessibility that gives due importance to accessibility factors.

Museums are currently creating Web sites. The question arises as to what should be the role of museum Web sites? Should each be a separate entity from the museum itself? Should the Web site be a mere advertising medium for a museum?

Education

In a country as large as India, only 25 university departments across the country conduct archaeological field-work and offer post-graduate education on the subject. Even in the national capital, none of the prestigious universities has a full-fledged department of archaeology at the undergraduate or postgraduate level.^[104]

There is a need for setting up full-fledged departments of archaeology at universities for teaching and research.

Presentation techniques

Museums in India are not updating their presentation techniques due to lack of funds and training of the curators. New lighting methodologies have been adapted in national museums and other large State museums. But all small museums, such as the district level museums, school and college museums do not have adequate funds for updating the museums.

Conservation

Major museums have their own conservation laboratories. There are also regional conservation laboratories in various regions. But they are inadequate to meet the needs of existing museums. There is a need for more conservation laboratories to serve the increasing number of museums.

Conservation of Extinct Species of Wild Animals. India once had rich biodiversity that has become considerably depleted. The question arises as to how this fall in biodiversity can be checked and also reversed.

Project Tiger was launched in 1973 to provide tigers an opportunity to breathe and grow in their natural habitat. However, as administration focus has dwindled and priorities have changed, implementation of the program has certainly suffered and funds sanctioned for Project Tiger have also not been properly utilized. There is a need for such projects to cover other species as well that are facing extinction.

Present Situation

India is a country that is rich in culture, heritage, science and artifacts. Its museums and art galleries house a great cultural heritage. The National Museum, New Delhi is the top museum in the country. In addition to State museums and art galleries, there are a large number of art museums and galleries (non-commercial) that display India's rich heritage. Strengthening and modernization of museums in four metros, namely, Delhi, Kolkata, Mumbai, and Chennai is taking place under the 11th five year plan (2007–2012). Hopefully, this will lead to resurgence of Museums and Museology.

India also has a rich biodiversity. The country possesses bountiful forest areas that display the richness of species and the range of habitat types. The National Zoological Park, Delhi, is the finest Zoological Gardens in India. Some of the best jewels of Indian wilderness include the Great Himalayan National Park in Himachal Pradesh, Dachigam National Park near Srinagar, Corbett National Park in Uttar Pradesh (which is also a famous tiger reserve), Ranthambore National Park in Rajasthan, and Sundarbans National Park in West Bengal, and Kaziranga in Assam (the land of rhino).

CONCLUSION

With a population of over one billion, India is the world's largest democracy. It has a large pool of talents with over 620 million people of working age. Its economy is growing at an average rate of 8%. With booming IT services, state-of-the-art communication, and fast growing service industries, India is poised to become a global power.

Convergence of Libraries, Archives, and Museums

There are certain areas and issues of common interest among the three fields of specialization. Areas of common interest include acquisition, organization, preservation, and digitization of documents, designing of Web sites, organization of exhibitions, display of items, management problems, status in the society, etc. These areas can serve as a starting point for a fruitful dialog. Today, the situation is such in India is that there is very little interaction between these three areas.

There is little convergence happening in India. The National Mission for Manuscripts is an example of convergence, where libraries, museums and archives are involved in the effort. The post of Librarian at Jawaharlal Nehru University was advertised recently, the desirable qualification was M.Phil./Ph.D. degree in library science/information science/documentation/archives and manuscript-keeping. This is a step toward convergence. There are very few examples of this kind.

There is a need to create linkages across different kinds of information institutions in India. Librarians, archivists, and museologists need to work out common strategies for making collections accessible and facilitating inter-linkages between different kinds of collections. Plans for common content strategies can be worked out in various programs and projects involving digital work. In fact, there are common problems faced by information professionals, such as that new materials often are in unstable digital formats.

They should work together joining hands to do a better job, in spite of differences in focus, practices, perception, standards for digital format, etc. It may be kept in mind that often users want information, rather than a specific

book, an archival folio, or a museum object. Let there be cross-fertilization of ideas, practices and experiences. This will do a lot of good for information professionals and institutions in India.

Cooperation among Information Institutions

There are some ongoing projects involving cooperation among information institutions such as the Digital Library of India, National Mission for Manuscripts, etc. The Digital Library of India is hosted by the Indian Institute of Science, Bangalore in cooperation with CMU, IIIT, NSF, ERNET, and MCIT for the Government of India and 21 participating centers. The National Mission for Manuscripts was launched in February 2003 by the Ministry of Culture, Government of India, to save the manuscripts, one of the most valuable but less visible cultural heritage. The main aim of the mission being to create an electronic database of manuscripts.

Trends

In memory institutions, there is a definite shift in emphasis toward access to information instead of ownership of information. Digitization of documents has helped in this shift. Computerization of libraries, archives and museums is taking place. All major information institutions have their own Web sites. Large number of digital libraries have been designed. Museums are putting out digital exhibitions and digitizing their collections. Archives are also digitizing their collections.

Digital libraries in information institutions are beginning to become the center of information services. Information institutions are increasingly participating in creating open sources. The open source movement in India is getting quite strong. These are healthy signs.

Issues

The question arises, are the graduates being produced by the schools of library science, archival science and museology employable? The quality of graduates being turned out in India leaves much to be desired. The quality of education needs to be improved to bring it up to the international level.

There is not enough financial support available for the information sector. However, there are signs that in the 11th five-year plan (2007–2012), the Government of India is committed to providing better support for preserving the national heritage and making it accessible to the people.

Lack of a good image is a matter of concern. Improvement in quality of education can go a long way in this respect. In addition, the theoretical basis of the disciplines of library science, archaeology and museology needs to be strengthened, so that they are considered on a par with other disciplines in higher education.

Abstract

Indigenous librarianship unites the discipline of librarianship with Indigenous approaches to knowledge, theory, and research methodology. It has a developing bibliography and local, national, and international professional associations devoted to its growth. A focus of Indigenous librarianship is the provision of culturally relevant library and information collections and services by, for, and with Indigenous people. Grounded in the contemporary realities of Indigenous people and Indigenous aspirations for self-governance and sovereignty, it has a critical theoretical base. Its practice may be carried out in spaces from small Indigenous community libraries to specialized collections in large research institutions. As an emergent scholarship the field is in the process of defining itself. This entry serves as an introductory overview to the history, practice, issues, and theoretical approaches associated with Indigenous librarianship.

INTRODUCTION

Indigenous librarianship unites the discipline of librarianship with Indigenous approaches to knowledge, theory, and methodology. It emerged as a distinct field of practice and an arena for international scholarship in the late twentieth century bolstered by a global recognition of the value and vulnerability of Indigenous knowledge systems, and of the right of Indigenous peoples to control them.^[1,2] Its growth converges with the development of Indigenous research paradigms that place Indigenous control, benefit, and values at the center of research.^[3] The field of Indigenous librarianship is rooted in long-standing and established practices that Indigenous peoples employ to create, transmit, and preserve knowledge. These practices maintain Indigenous cultural and social systems and provide protocols for ownership and the appropriate use of community knowledge.^[4,5]

Indigenous librarianship has a developing bibliography and local, national, and international professional associations devoted to its growth.^[6] Its foundations rest on strong understandings of the concerns of Indigenous people about the intersections between Indigenous knowledge and culture, and library and information science. Indigenous cultural principles are considered critical to restoring and continuing the principles of Indigenous knowledge management and sharing. Indigenous librarianship

encourages the broader profession to move beyond its own disciplinary knowledge base and engage in multidisciplinary approaches with Indigenous cultural experts, information technology (IT) developers, governments, and other institutions.^[7]

The purpose of the entry is to survey this protean field through establishing its social and historical contexts, profiling leading practitioners, and highlighting some of the key issues. This entry focuses on Indigenous librarianship within the United States and Canada, and is informed by Indigenous scholarship in Aotearoa/New Zealand and Australia with reference to other international initiatives in order to give a sense of the breadth and the diversity of the provision of library and information services by, for, and with Indigenous peoples. As an emergent scholarship, the parameters and scope of Indigenous librarianship are fluid and although it has a rich discourse there is as yet no codified definition of the field. This entry therefore describes some of the features and begins to map the landscape of Indigenous librarianship.

Methodology

The reality of the practice of Indigenous librarianship is underreported and exists beyond the literature: it exists in the lives of those who work directly with Indigenous peoples.^[8] Indigenous library workers who often work outside

of the mainstream and librarians in Indigenous cultural and collecting institutions that are outside of state or public systems are the “local heroes” who serve as a link between the past and present generations.^[9] This entry incorporates a biographical approach in order to recognize and celebrate the achievements of Indigenous librarians and library workers. This approach is informed by Indigenous research methodologies that strive to surface the contributions and legacies of Indigenous people, and aligns with Linda Tuhiwai Smith’s Indigenous projects of testimony, storytelling, sharing, and returning.^[10]

Terminology

The original inhabitants of North and South America, Australasia, Africa, and Asia are often identified as a type of collectivity that is seen in contradistinction to the Western or dominant society. Terminology that represents this collectivity includes words such as *Tribal*, *Native*, *Aboriginal*, and *Indigenous*. Original inhabitants within a specific country are culturally and linguistically diverse although they may also be classified as a single group within their countries. The terminology used by the state often reflects a classification established by the force of law within a country and imposes external concepts of identity that may or may not be accepted by an Indigenous individual or collective. This is a complex area with its own literatures and discourses where meanings are constructed in legal, social, cultural, and political contexts.^[11] In addition to specific names of nations, communities, cultural, and language groups, there are various generic terms used to denote Indigenous peoples.

In Canada the term Aboriginal is defined under Section 35 of the Constitution Act (1982) to include Indian, Métis, and Inuit peoples. For the purposes of this entry it is used more broadly to include all First Nations, status and non-status Indians, Métis, and Inuit people. First Nations is a term that arose in the 1970s to replace the word “Indian” which is sometimes considered offensive, and refers to a body of Aboriginal people with a shared national identity. First Nations is also used to replace the word “band,” a term defined by the Indian Act to mean a body of people defined as Indian by the government. A status Indian is a person who is registered as an Indian under the Indian Act; conversely a non-status Indian is a person not registered as an Indian under the Indian Act. Métis people are of mixed First Nations or Inuit and European ancestry who may also identify as a nation, often the Métis Nation within Western Canada.^[12]

Within the United States, the collective term Native American may include American Indian, Alaska Native, and Native Hawaiian. In Canada, the United States, Australia, and New Zealand, Indigenous people claim the right to define their own cultural identity and membership and may not accept the definitions of the state. Within international arenas, the term Indigenous peoples is pluralized to

denote the great diversity among Indigenous groups at the same time as it serves as a collective term. Indigenous peoples are seen to be

the inheritors and practitioners of unique living cultures and ways of relating to other people and to the environment who have retained social, cultural, economic, and political characteristics that are distinct from those of the dominant societies in which they live.^[13]

INDIGENOUS PEOPLES AND LIBRARIES

The United Nations (UN) estimates that there are 4000 to 5000 Indigenous cultures existing in the world, and over 370 million individuals belonging to these cultures, living in more than 70 countries.^[14] This enormous cultural and linguistic diversity among Indigenous peoples belies a shared common experience of historic and ongoing colonialism. Indigenous peoples globally continue to face the ongoing effects of the dispossession of their lands, languages, cultures, and knowledge. Many Indigenous people face economic marginalization, lack of access to social services and educational opportunities, and racial discrimination. Consequently, Indigenous people share concerns relating to the protection of their rights, lands, resources, and their cultural and intellectual property. As Lynette Russell, Director of Monash University’s Centre for Australian Indigenous Studies observes, “The First peoples in Aotearoa/New Zealand, Canada, the United States of America along with many other Indigenous peoples face similar issues relating to access to, and control of, information about their cultures and communities.”^[15]

United States

According to the 2000 census, 4.1 million American Indians and Alaska Natives comprise 1.5% of the total population of the United States.^[16] Approximately one-third live on one of 300 reservations with the remainder living in urban and rural areas. The population is young in comparison with the general population. One-third of the population lives below the poverty line, experiencing lower high school graduation rates, and less presence in higher education.^[17] There are 175 Indigenous languages spoken in the United States however, 55 are spoken by fewer than 10 people; 70 are spoken only by Elders; and only 50 of them are spoken by two or more generations. As in other countries, Indigenous language loss is considered a key factor in cultural erosion, and Native language maintenance and revitalization are a high priority.^[18]

The relationship between Native Americans in the United States and librarianship is fundamentally different from that of other cultural groups because tribal nations have a formal relationship with the federal government. This relationship is set out in treaties and court decisions

intended to assure tribal groups of certain benefits, such as, health, education, and general welfare.^[19] Although education is a treaty right of American Indians in the United States, and access to libraries and information is integral to the education process, library services to reservations were not available until the 1970s.^[20] During the 1970s, fostered by a convergence of changes in federal legislation, court decisions, and an increased receptivity to American Indian self-determination efforts, tribal libraries slowly began to develop. The National Commission on Libraries and Information Science (NCLIS) hearings in 1974 examined library services to urban and on-reserve American Indians and identified the great need in these communities and an “abysmal” lack of formal policy. The *White House Pre-Conference on Indian Library and Information Services On or Near Reservations* (1978) brought together 103 tribes to lay the groundwork to improve library services for American Indians and shape U.S. Federal library and information policy. Native Americans actively promoted and advocated for tribal libraries, the spaces that foster and preserve cultural heritage and protect a tribe’s heritage for future generations, which were a keystone in this national library service framework. Tribal libraries support oral traditions through preservation programs and the dissemination offered by print and new media. They also serve the educational, informational, and recreational information needs of Native Americans and provide vital access to government data that supports self-governance activities.

Nonetheless, the comprehensive NCLIS report *Pathways to Excellence: A Report on Improving Library and Information Services to Native American Peoples* (1992) documented inadequate library services for Native Americans characterized by discrimination and lack of culturally appropriate services for off-reserve populations, and geographic barriers to access on-reserve.^[21] Ten challenges were identified for the development of tribal libraries: consistent funding at federal, state, local, and tribal government levels; training and technical support for Native American communities; relevant collection development; improved access; state and local partnerships; identification of model programs; the expansion of the tribal library program to include museum and archival services; support for literacy and job skills training; support for IT; and the establishment of federal responsibilities.

Currently, support of tribal libraries crosses multiple jurisdictional boundaries: tribal, local, county, state, regional, and federal. Each represents potential revenue streams to buttress tribal library sustainability and capacity building. At the federal level, the Institute for Museum and Library Services (IMLS) pursues a multidimensional strategy including basic noncompetitive support for local tribal libraries, enhanced support for innovative developments within tribal libraries, national leadership initiatives designed to promote collaborative efforts and develop best

practices, and funding capacity building diversity scholarship program initiatives such as Knowledge River at the University of Arizona and Honoring Generations at the University of Texas, Austin. At the state level, some examples of tribal library initiatives are found in Arizona, New Mexico, Montana, and Oklahoma. The Arizona Gathering of Tribal Librarians is currently planning its seventh Gathering for the Spring of 2008, and a Tribal Library Consultant is employed within the Arizona State Library, Archives and Public Records. The New Mexico State Library’s Tribal Libraries Program (TLP) includes the TLP Direct noncompetitive grant for tribal libraries^[22] and the Indigenous Nations Library Program (INLP) at the University of New Mexico.^[23] In Montana, the Tribal College Librarians Professional Development Institute has been held annually since 1990 at Montana State University in Bozeman.^[24]

The Tribal Archives, Libraries and Museums conferences held biannually since 2003 are excellent examples of cross-jurisdictional collaboration in support of the development of tribal libraries. Originating from an IMLS National Leadership Grant awarded in Arizona in 2003 and 2005, the concept was expanded through an IMLS Laura Bush Librarians for the twenty-first Century Grant to the Western Council of State Libraries for 2007–2009. The Oklahoma Department of Libraries hosted the 2007 National Tribal Archives, Libraries and Museums Conference. Four National Immersion Institutes followed in 2008, one each focusing on Archives, Caring for Native American Objects, Photographic Preservation, and Tribal Libraries. The final conference of this grant cycle will be hosted by the Oregon State Library and Tamástslikt Cultural Institute in Oregon in 2009.^[25] The ability to create these platforms for collaboration and professional exchange are essential to the development, definition, and vitality of the emergent field of Indigenous librarianship. They provide the opportunity to discuss issues from Indigenous standpoints, meet other practitioners, and allow Indigenous librarians to center their practice within their ways of knowing (Fig. 1).

Canada

Canada’s Aboriginal population is young and growing six times faster than the general population. It is now over 1 million. The increase may be attributed to a variety of factors, including tendency to self-identification, birth rate, and legislative changes in definitions. The Aboriginal population consists of approximately 60% First Nations people, 33% Métis people, and 4% Inuit who live primarily in the Arctic regions. Over half of the Aboriginal population lives in urban areas. By 2017 it is projected that the Aboriginal young adult population (aged 20–29) will comprise one-third of the young adults in the province of Saskatchewan; 24% in Manitoba; 40% in the Yukon Territory and 58% in the Northwest Territories.^[28] In Canada

Fig. 1 Profile: Lotsee Patterson.

Dr. Lotsee Patterson, an enrolled member of the Comanche Nation raised on her mother's allotment in southwestern Oklahoma, is Professor Emeritus at the University of Oklahoma School of Library and Information Studies. Dr. Patterson is a founder and past president of the AILA. She is a well-known lobbyist for national legislation to fund and improve library services to United States tribes, and for helping to establish tribal libraries in the United States. Beginning in the early 1970s, Dr. Patterson wrote successful grant applications to hold training institutes for American Indian library aides, believing that training staff would pave the way for tribal libraries. Patterson carried out a series of groundbreaking tribal library demonstration projects in the 1970s, eventually publishing the seminal TRAILS (Training and Assistance for Indian Library Services) manual in 1984, a key resource for tribal librarians. Dr. Patterson cochaired both the 1979 and 1991 Native American preconferences to the White House Conference on Library and Information Services, and has mentored hundreds of American Indian librarians and students throughout her career while persistently spotlighting the critical need to fund tribal libraries and commit resources to library services for American Indians. In 2005, Dr. Patterson was recognized as "one of the most outspoken advocates for equitable library services for American Indians" with an honorary ALA membership award for her outstanding and lasting contributions to the field of librarianship.^[26,27]

there are 615 First Nations, 10 unique language families and over 60 different Aboriginal languages spoken in the country although, many Aboriginal languages in Canada are endangered or have been lost. The Indian residential school system which operated from the nineteenth century to the 1980s resulted in the dislocation of Aboriginal families, communities and cultures, and in the loss of Aboriginal languages. The ongoing intergenerational impacts of the residential school system continue to be felt today.^[29] On June 11, 2008, the Prime Minister of Canada and the Federal party leaders issued an official apology to the Aboriginal people of Canada for the damage and suffering caused by the assimilationist policies of the Canadian government.^[30] The courage and resilience of Aboriginal people and the strengths of Aboriginal cultures were acknowledged, and a Truth and Reconciliation commission established to foster reconciliation between Aboriginal people and all Canadians, and to rectify the public historic record of the past.

Public library services for Aboriginal people are uneven across the country. In some provinces, jurisdictional issues are cited as a rationale for the lack of free access to the public library system for Aboriginal people. As First Nations and Métis people are considered federal jurisdiction^[31] and public libraries are often funded at the municipal level, the principle of universal access to public institutions does not extend in practice to Indigenous peoples. In British Columbia (B.C.), there are no public

libraries on reserve, and the libraries that do exist on reserve are generally small, underfunded band council collections, and band school libraries.^[32] In Ontario, the provincial government contributes to the development of public libraries in First Nations communities. However in 2001–2002, only 52 of 141 First Nation libraries in Ontario received operating grants, and because the operating grants are based on population size many small communities are underfunded.^[33] Among First Nations communities, libraries are not always a priority when there are pressing needs in the areas of rights and title claims, infrastructure, education, and health. A First Nations library worker explains: "We need all our money to fund our land claims. If we don't have land, we don't have community. If we don't have community, we don't need a library."^[34]

The province of Saskatchewan is among the leaders in developing equitable, culturally relevant Aboriginal library and information services in Canada. The Saskatchewan Minister's Advisory Committee on Library Service for Aboriginal people report, *Information is for Everyone* (2001), makes 46 recommendations for improved library and information services for Aboriginal people. It highlights universal access to library services for all Aboriginal people, including on-reserve and off-reserve; partnerships for equitable access; increased awareness, and public education regarding Aboriginal people.^[31] A key recommendation, similar to repeated earlier ones in Ontario service reviews, is that First Nations retain control of library services on reserve, and responsibility for determining the kind of library services on reserve. The Library Services for Saskatchewan's Aboriginal Peoples Committee is composed of Aboriginal and public sector representatives who meet six times a year to advise on the implementation of the recommendations.

Public libraries in urban centers tend not to differentiate between Aboriginal people and the general population. As a consequence urban Aboriginal peoples are often not well served. There are exceptions, such as the Albert Library branch of the Regina Public Library^[35] and the Spadina branch of the Toronto Public Library that work closely with the local urban Aboriginal communities. The Edmonton Public Library conducted a survey in order to improve library services and programs for the urban Aboriginal community in Edmonton. The final report, *Library Services to Aboriginal Peoples: Task Force Report* (2005), includes an environmental scan with recommendations.^[36]

At the national level, a Library and Archives Canada national consultation on Aboriginal library services resulted in a report that included 10 focus areas for improvement in the areas of consultation and partnerships; funding and resources; jurisdiction; planning and administration; universal and equitable access; education and training; advocacy; promotion; authenticity of voice; and outreach and networking (Fig. 2).^[37]

Fig. 2 Profile: Charles Angus Cook (Thawennersere) (1870–1958).

The tenacity and vision of Charles Angus Cook (Thawennersere or Da-ha-wen-nen-se-re), a Kanesatake Mohawk, set a standard for the aspirations of Aboriginal library services in Canada. Da-ha-wen-nen-se-re (Charles Cook) worked for the Canadian Indian Affairs Records Branch from 1893 to 1926 as a clerk who classified documents relating to Indians in Canada, and as a translator who translated Iroquois dialects into English. Early in his career he envisioned and advocated for a National Indian Library. He also lobbied tirelessly for the development and proper organization of the Department of Indian Affairs' collection of Indian materials and recommended supplementing the government collection with materials contributed by Aboriginal people in order to reflect Aboriginal perspectives and understandings. He recommended free access to the collections for departmental staff and for all status Indians. In later years, Da-ha-wen-nen-se compiled a Mohawk dictionary and published a Mohawk language newspaper, *Onkweonwe*, the first newspaper in Canada to be produced and published solely by an Aboriginal person.^[38]

Australia

Aboriginal Australians and Torres Strait Islander people are two culturally distinct Indigenous peoples of Australia. The Torres Strait Islanders are the traditional inhabitants of the Torres Strait Islands which lie north of Cape York, Queensland; Aboriginal people are located primarily in mainland Australia, including Tasmania. In 2006, 2.5% of Australia's total population of over 21 million are identified as Indigenous.^[39] The Indigenous population in Australia is growing rapidly and is also young; 39% are under 15 years of age. While the largest proportion of Indigenous people live in urban areas (30%), a high proportion live in Outer Regional (23%), Remote (9%), and Very Remote (18%) areas when compared against national statistics.^[40]

Before European contact, Indigenous peoples in Australia comprised over 500 different language groups. Beginning in the late 1700s, British colonization violently suppressed Aboriginal cultures: colonial legislation regulated segregation, restricted movement, and forcibly removed children from their families.^[41] The Australian government's *Bringing Them Home* report (1997) documented the impact of over 150 years of these policies that dislocated families, impacted physical and mental health, resulted in losses of language, culture, and connection to traditional land. On February 13, 2008, a historic parliamentary vote adopted Prime Minister Kevin Rudd's apology on behalf of all Australians for the harm done to the Indigenous people of Australia.^[42]

A 1993 report revealed that Australian Indigenous library services relied on erratic grant funding and were usually initiated by community or educational organizations.^[43] A year later, an Indigenous Advisory Committee

was established to assist with the development of equitable access and inclusive services. The Library and Information Service of Western Australia (LISWA) generated a number of Indigenous-focused service plans aimed at improvement, including *Public Libraries: Good Places for Aboriginal People* (1995) and *Services to Aboriginal and Torres Strait Island Peoples* (1997).

The State Library of Queensland, acknowledging that Indigenous Australians had been "denied, excluded, and/or discouraged access," implemented an Indigenous Library Services Strategy in 2002 focusing on the establishment of Indigenous Knowledge Centres (IKCs) in remote communities, improving public library services, raising the profile of Indigenous people in libraries particularly the State Library, and increasing employment and training opportunities.^[44] By 2008, the State Library of Queensland had established 17 IKCs in partnership with Indigenous communities who own and manage the IKCs. An IKC is a community space that offers traditional library services and can be located in community Keeping Places and small museums. In addition to the initial setup costs, the State Library of Queensland provides ongoing support to IKCs in the form of training and development support, and community training programs to help preserve and share local Indigenous Knowledge, orally and digitally, and access cultural material in collecting and cultural institutions throughout the world. The State Library of Queensland has established the first Indigenous Knowledge Centre in a State Library called *kuril dhagun* which welcomes Indigenous and non-Indigenous people to engage with traditional and contemporary expressions of Queensland Indigenous knowledge. The Library has been instrumental in the development of the *National Policy Framework for Aboriginal and Torres Strait Islander Library Services and Collections*,^[45,46] as well it has developed its own policies and strategies on reconciliation, cultural protocols, language preservation and maintenance, public library services, and employment and training in the library and information sector.^[47]

In 2006, an evaluation of the Northern Territory's Libraries and Knowledge Centre (LKC) model led by Dr. Martin Nakata, a Torres Strait Islander, and Director of Indigenous Academic Programs at Jumbunna Indigenous House of Learning, University of Technology Sydney, concluded that the model had the potential for extension across the Northern Territory.^[48] The model incorporates Indigenous knowledge as part of a community-centered information and knowledge base to support the goals of community-building through libraries, and the provision of sustainable public library services that are relevant to multilingual, clan-based, Indigenous communities. Indigenous knowledge centres are also being established in Africa, Latin America, and Asia to revitalize endangered cultures and languages, contribute to economic development, and center Indigenous planning and development (Fig. 3).^[49]

Fig. 3 Profile: Joe Gumbala.

Joe Neparrnga Gumbala, a Gupapuyngu Yolŋu Elder and musician from North East Arnhem Land is a leading authority on Yolŋu intellectual and legal traditions. Gumbala is respected for his Yolŋu knowledge and his ability to interpret other knowledge systems using traditional frames of reference.^[50] As a Community Liaison Officer at the Galiwin'ku Indigenous Knowledge Centre in northeast Arnhem Land, Gumbala travels throughout Australia locating collections of Yolŋu family histories and other cultural heritage materials, and returning digital copies to Gupapuyngu communities for local access. Gumbala applies the Yolŋu traditional knowledge organization systems to the management of the knowledge centre's digital collections. Yolŋu knowledge, ceremony, and law have three strata—restricted, peri-restricted, and public. All Yolŋu materials are bound by these access and ownership principles. Kinship relations define related secondary rights to intellectual and physical property, and determine access to both historic and contemporary Yolŋu materials at the Galiwin'ku IKC.^[51]

Aotearoa/New Zealand

Māori people are the *tangata whenua* (“indigenous people”) of New Zealand. The Māori call their traditional lands Aotearoa, Land of the Long White Cloud. In Aotearoa/New Zealand, Māori people represent about 15% of the population and are expected to reach 21% by the year 2051. Like many Indigenous people, Māori are increasingly urbanized, and they experience social and economic challenges, including comparatively high unemployment, incarceration, and mortality rates, and lower outcomes in educational achievement, health, and income.^[52]

The colonization period in Aotearoa/New Zealand began during the mid-nineteenth century after the signing of the Treaty of Waitangi in 1840. Signed by over 500 chiefs, the Treaty of Waitangi guaranteed ongoing ownership of lands, fisheries, and other possessions to the Māori, and granted full British citizenship to the Māori. The orthography of the early missionaries was readily adopted by the Māori and resulted in a significant body of manuscript and printed materials written in the Māori language. In 1975 a permanent commission of enquiry, the Waitangi Tribunal, was established to address ongoing infringements on Treaty of Waitangi provisions and enable Māori people to contest breaches of promises and make claims. Evidence used in Treaty claims frequently relies on the documentary materials held in libraries and archives throughout Aotearoa/New Zealand. The Tribunal has been instructed to make its decisions based on both the English and the Māori text. Māori access to library and archive holdings is therefore central to the ongoing settlement of Māori claims and to the national reconciliation process. In addition, libraries and archives in New Zealand also play a central role in supporting Māori language revitalization efforts.

This socio-legal background sets the stage for Indigenous librarianship in New Zealand and for understanding the development of the Ngā Ūpoko Tukutuku/Māori subject headings and their role in the provision of access to Māori collections for and by Māori people.

In 1993 the Library and Information Association of New Zealand Aotearoa (LIANZA) initiated a two-phase national research project on biculturalism issues and services to Māori, *Te Ara Tika* (translated as “the right path”). The first phase undertook an analysis from the perspective of the library profession; the next phase surveyed Māori information needs and Māori opinion about libraries and library services. The findings are documented in *Te Ara Tika Guiding Voices* report (1997) which identified strong Māori interest in library and information services within six dominant themes that emerged as intellectual access and information literacy; relationships between youth literacy, libraries, and schools; Māori staffing; establishing libraries in Māori communities; and intellectual property issues. These findings echoed a 1960s report conducted by the New Zealand Library Association, and the replication of results highlights a persistent Māori interest in library-centered issues.^[53]

The library community's response to *Te Ara Tika Guiding Voices* report has included the National Library of New Zealand's *Te Kaupapa Mahi Tahi—A Plan for Partnerships* (2001), a renewable five-year plan focused on the National Library's service to Māori. It also includes the Manukau Libraries' *Te Ao Marama* (2002), a Māori service strategy from one of the country's largest public libraries. In addition, a new National Library Act (2003) was passed that acknowledges Māori interests in library collections and services: it specifically references Mātauranga Māori (Māori knowledge), and has established the Library and Information Advisory Commission Ngā Kaiwhakamārama i ngā Kohikohinga Kōrero (LIAC) as an advisory body on the role of library and information services in the social, cultural, and economic life, including Mātauranga Māori. The LIANZA includes knowledge of Mātauranga Māori and the Treaty of Waitangi as essential components of professional competence for the library and information sector (Fig. 4).

Indigenous Libraries and Their Intersections

From Māori perspectives the past and the present are seen as a continuum: the past is a taonga (knowledge/treasure) to understand the present, to learn and grow from. The past forms part of the Māori living traditions that connect Māori to their past, and to their identity.^[56] Traditional taonga knowledge comes in many forms: it may be carried in carving, woven into wall panels, as well as inscribed in early Māori writings, archival documents, and other forms of transmission. For millennia Indigenous peoples have passed on their unique legacies through the chain of oral tradition. It is transmitted through habits and customs as

Fig. 4 Profile: Chris Szekely.

Chris Szekely served as a lead on the *Te Ara Tika Guiding Voices* national research project on library and information services for Māori, and has written widely in support of improved library services for Indigenous New Zealanders and on issues related to Indigenous librarianship. On March 19, 2007, Mr. Szekely became the first Māori Chief Librarian of the Alexander Turnbull Library, a division of the National Library of New Zealand and the country's leading heritage research library and storehouse of the nation's documentary collections. One of his first tasks is to provide leadership on a major expansion of the facility to be completed in 2011.^[54] Prior to this appointment, Chris Szekely served as City Librarian at Manukau City Council heading one of the largest and fastest growing public library service regions in New Zealand. During his tenure as City Librarian, he opened a number of new branches, including one designed with and for Pacific Islander youth, and established a bilingual catalogue and Web site for the library.^[55] He is a founding member of Te Rōpū Whakahau, the National Association of Māori library and information workers, and was instrumental in the formation of the International Indigenous Librarians' Forum (IILF).

well as through those Elders who serve as the living libraries of their communities: the carriers of knowledge of traditional governance, science, technology, philosophy, values, healing, and history. This type of knowledge is often largely undocumented and Indigenous peoples are developing more permanent structures such as libraries, and utilizing new media technologies, to protect and preserve it. At the same time Indigenous nations require access to all of the information resources and technologies required for self-governance and activities related to education, social services, economic development, law, and environmental issues in the twenty-first century.^[21]

Indigenous understandings of knowledge continua are sometimes manifest in institutional convergences between libraries, archives, and museums. As a function of both worldview and resource constraints, Indigenous libraries may traverse the conventional institutional boundaries separating library–archive–museum and creatively converge these institutions for Indigenous purposes. The locations of knowledge centers may range from an ecotourism center to a school media center, or postsecondary academic library, to a literacy program, treaty office, health services unit, or urban friendship center. There is extensive variation in locale, clientele, services, and governance and with the local and external institutions with which they intersect (Fig. 5).

KEY ISSUES IN INDIGENOUS LIBRARIANSHIP

While the practice and the location varies, a focus of Indigenous librarianship is the provision of culturally relevant library and information collections and services for

Indigenous people. Within Indigenous communities there are standard information requirements in addition to unique information needs that are related to the maintenance and revitalization of Indigenous cultures and languages; Indigenous self-governance; rights and title claims; stewardship of traditional territories and resources; preservation of traditional knowledge systems; and the protection of intellectual and cultural property. The web of service provision ideally begin with Indigenous-controlled libraries in Indigenous communities and extends to the networks of small, rural, urban, academic, legal, special libraries, archives, and other institutions. All of these sites offer rich ground for the development of practice, theory, scholarship, and methodology in Indigenous librarianship. Several overarching themes that recur in practice and in the literature have been selected as key issues for Indigenous librarianship under the umbrella concepts of library development, access, and intellectual property. The development of Indigenous-controlled libraries and other forms of memory institutions is fundamental for Indigenous cultural and intellectual sovereignty. Social justice demands that Indigenous people have equitable access to public institutions and their resources. Equitable access includes a range of considerations including resolution of jurisdictional barriers, the provision of culturally appropriate and meaningful collections and services, and development of accurate knowledge representation tools: these may be bilingual or multilingual depending on the locale and clientele. Public institutions have a responsibility to staff their services with a diverse staff that represents the clientele being served and to explore innovative measures to ensure diversity. Prerequisites to the provision of equitable access include the basic infrastructure and skills to utilize library services and collections, such as Internet access, telecommunications, and multiple literacies. Literacy forms pathways composed of skills and knowledge that facilitate various levels of access to the resources offered by libraries and is therefore a fundamental issue for Indigenous librarianship. The protection of and protocols for use of Indigenous cultural and intellectual property (ICIP) guide the design of appropriate services, and collections and inform standards of professional ethics: virtual repatriation, an emergent area within the field may be included within this purview.

Indigenous Libraries

Against the odds Indigenous libraries endure and continue to grow. Although diverse in form, size, purpose, and location, Indigenous libraries share many similar challenges: they often compete for funds with basic services, such as roads, utilities, and more urgent priorities on reserve and are staffed by nondegreed personnel with little training.^[57] Perennial funding challenges contribute to high staff turnover, inadequate facilities, and a lack of

Fig. 5 Profile: Gene Joseph.

Gene Joseph, Wet'suwet'en Dakehl, has been involved in developing First Nations libraries in Canada for many years. She also manages First Nation litigation research for cultural and legal issues, and served as the librarian for the Gitksan Wet'suwet'en in the precedent setting Delgamuukw case in the Supreme Court of Canada. Gene Joseph reflects on her experiences during this landmark trial.

"On December 11, 1997 the Supreme Court of Canada handed down its decision in the court case Delgamuukw vs. British Columbia, [1997] 3 S.C.R. 1010 which affirmed the inherent meaning of aboriginal title. It was also the first court to rule that oral history or oral evidence be placed on equal footing with that given to historical documents.

In 1984 two First Nations, the Wet'suwet'en and the Gitksan, filed their statement of claim to 58,000 km² which was divided into 133 territories with traditional ownership accorded to 71 Houses of the Gitksan and Wet'suwet'en people.

In 1982 I had graduated from the University of British Columbia School of Library and Archival Sciences and it was an honor to me that in 1984 I was recruited by the Gitksan and Wet'suwet'en to work on a collection of oral history materials from the elders and chiefs. I returned to my home in Hagwilget, a Wet'suwet'en village near Hazelton. There, I worked on the oral evidence with senior Gitksan and Wet'suwet'en researchers: oral evidence was thoroughly reviewed, transcribed, and translated by the chiefs and elders.

In 1986 Mass Gaak (Don Ryan) again recruited me to return to Hazelton, this time to work on the historical documents that had been collected as evidence. I continued to work through the trial. The trial ran for 374 days starting May 11, 1987 and ending February 7, 1990. The trial had 9200 exhibits with thousands more documents previously listed in numerous document lists, and 26,000 pages of transcripts. The decision was handed down on March 8, 1991. This was followed by the B.C. court of Appeal. This decision came down on June 25, 1993 and was appealed by the Gitksan and the Wet'suwet'en to the Supreme Court of Canada, which rendered its decision on December 11, 1997.

Delgamuukw drew upon the technical skills I had learned at the Union of B.C. Indian Chief's Library, and the organizational, archival, and computing skills learned at Library school. The oral recordings needed to be preserved and treated as archival as they recorded people who were in ill health or quite elderly. Their knowledge was invaluable. The case started just as personal computers began to be introduced into office environments, which in turn required the development of new software programs, database structures, and the incorporation of continually developing and advancing hardware and software. The Delgamuukw Gisdawwa case was one of the first court rooms in Canada to use personal computers by the court and counsel.

Historical documents had been collected from various archives in Canada, England, and the United States. There were numerous scientists from various fields: archaeologists, anthropologists, linguists, historians, geographers, and genealogists gave evidence and presented documents. Therefore the language, classification, and headings covered many streams of knowledge, both Western and Indigenous. Litigation support as well drew upon court requirements, counsel's needs, and court reporters which were in the throes of moving from the traditional hard copy to an electronic court room.

Most of all, the trial drew upon the knowledge of the traditional systems, history, and culture that I had learned from my family, and then from the elders and chiefs with whom I worked among the Gitksan and Wet'suwet'en people. While I did not speak the language, I was constantly surrounded and worked with sound and video recordings, translators, and linguists who were for the first time having to spell personal, place, and spiritual names. We worked closely with the cartographer as he recorded these names onto the new maps of the territories, continually cross-checking with the chiefs, elders, and researchers. The map was named "The map that roared" by the court.

collections and technology. Indigenous communities in remote areas face transportation and communications difficulties. These barriers to the development of Indigenous libraries have remained much the same over time, however, the priorities are changing due to the ubiquity of information and communication technologies (ICTs) in a global networked world. ICTs present the added challenges of an ever-changing technical environment that requires the acquisition and maintenance of hardware and software, the skills sets to utilize them, and broadband access. Even if funds are available, Internet connectivity may be inadequate in remote locations, and distance may also discourage the recruitment and retention of qualified IT staff.^[18]

Digital Divide

ICTs have been defined as "a diverse set of technological tools and resources used to communicate, and to create, disseminate, store, and manage information."^[58] The term digital divide is generally understood as the gap between ICT "haves" and "have-nots." It encompasses issues, such

as infrastructure and access to ICTs, use and barriers to use, and the critical role of ICT skills and literacy in an information society. From Indigenous perspectives ICTs support the revitalization of culture and language, and they serve as knowledge and communication building blocks that enable the development of community infrastructure in a range of areas from education to health, from economic development to environmental protection.^[59] They enable access to the global web of information, and perhaps more importantly they provide the means to participate in local and distributed communities of interest. As authorial tools ICTs have the potential to create and distribute Indigenous perspectives in order to correct some of the ubiquitous stereotypes and misrepresentations, to shape attitudes, and to change the ways in which history is understood. National information policy in Canada and the United States aims to provide affordable access to the Internet and to the skills required to use it. However, in the National Telecommunications Information Administration (NTIA) in the United States reported that only 9% of Native Americans in rural areas have home Internet access and that access tends to be through schools or libraries.^[60]

In Canada, the BC First Nations Technology Council research shows that in one-third of BC First Nations communities 75% of the homes are without Internet access, and in almost 20% of BC First Nations communities there are homes without basic telephone service.^[61] In Canada, the Community Access Program (CAP) is one of the primary federal connectivity programs that benefits Aboriginal communities and the Gates Foundation is making improvements to technology access, equipment, and support in both the United States and Canada. The digital divide, the ICT gap in access, services, and skills, however, continues to exist for Aboriginal people.

Profile: Jean Whitehorse

Jean Whitehorse, a Navajo member of the Towering House clan and Born for Bitter Water clan, is making a difference. As a training and outreach coordinator for the New Mexico State Library, Whitehorse conducts IT training at libraries and Navajo chapter houses in New Mexico. Exclaiming “get ready the world is going to change with or without you!” her advocacy has resulted in the hiring of more Native American trainers and in a new internship program for tribal college student ICT trainers working with the tribes. Whitehorse believes that as comfort with technology increases the tribal community members are empowered with new skills, and this in turn encourages the children, the future leaders, to explore the benefits of the virtual world. She draws an analogy between the artistry and expertise involved in weaving a Navajo rug and that of weaving technology education for the nations (Fig. 6).^[62]

This type of multidimensional model of ICT access underlines the many threads that must be woven together for effective use of technology, including political support at multiple levels, funding, perceived relevance to

Indigenous interests, culturally based evaluation and training, social relationships and skills sets.

Universal Access

Librarians have long upheld the principle of universal access to public libraries because as the UNESCO Public Library Manifesto states, “The public library, the local gateway to knowledge, provides a basic condition for life-long learning, independent decision-making and cultural development of the individual and social groups.”^[63] However, universal access to the public library is not a reality for Indigenous people in North America although it is a cornerstone of the national educational and information infrastructure in the United States and Canada. For Indigenous people who do “technically” live inside a library service catchment area, there continue to be many visible and invisible barriers presented through library practices, collections, and services. Many public institutions are seeking to improve their services for Indigenous people, after all, Indigenous people are community members in urban centers as well as in rural communities. Indigenous students, teachers, and faculty members populate the schools and academic institutions, and are within the ever-expanding circles of the digital community.^[64]

Literacy

From Indigenous perspectives the notion of literacy is conceptualized as being multidimensional one that may extend from an ability to read the land to an ability to read text. It includes the range of skills and knowledge required to read and interpret meaning, to allow deeper understandings, and ultimately to become the authors of new meaning. Indigenous approaches to literacy seek to honor and build bridges from existing knowledge and skills to strengthen Indigenous cultural identity, languages, and values. They are centered on local issues at the same time as they connect with an awareness of the global world. The legacies of cultural and language disruption left by colonial education systems and education designed for assimilation are integral to understandings of Aboriginal literacy and Aboriginal literacy education.^[65] Low text literacy levels are frequently a challenge in Indigenous communities. In Canada, the rate of illiteracy on-reserve is almost two times the rate of the off-reserve Aboriginal population and three times that of the general Canadian population.^[66] Within Indigenous contexts, it is important to acknowledge familial and social networks of authority and various types of literacy, in addition to English language text literacy. The relationships between ideas and knowledge, social practices, and responsibilities are considered to be important.^[67] English may be a second language for some learners, and for some learners Aboriginal English is the dialect used in the home, not mainstream English. Successful literacy strategies therefore

Fig. 7 Profile: Loriene Roy.

Loriene Roy is Anishinabe, an enrolled member of the Minnesota Chippewa Tribe, White Earth Reservation, and a Professor at the University of Texas at Austin School of Information since 1987. Dr. Roy has devoted her career to improving literacy and instruction services for Native youth, advocating for library services for and by Native communities, and supporting the education of American Indian librarians. Guided by Indigenous protocols and Anishinabe teachings in her teaching and writing, Dr. Roy is a respected and visible advocate for Indigenous perspectives on national literacy and library issues in the United States, and has been an active participant in international Indigenous librarianship gatherings, serving on committees that organized the first and second IILF in 1999 and 2001. In 2007, Dr. Roy became the first American Indian president of the American Library Association, a role she filled with the same spirit and vision that she brought to her presidency of the AILA in 1997–1998. In addition to her national and international leadership, she has served as the director of the Native American youth reading club program, “If I Can Read, I Can Do Anything” since its founding in 1999; established the “Honoring Generations” scholarship program for tribal librarians at University of Texas at Austin; assisted tribal schools with developing culturally responsive curriculum; created online resources for tribal college students; and inspired successive generations of American Indian librarians and students.^[68,69]

incorporate programming by and for Aboriginal people that are designed for a specific cultural clientele to develop the range of literacy skills required to succeed in education, and to succeed in integrating Aboriginal approaches to education into twenty-first century Indigenous pedagogies (Fig. 7).

Indigenous Knowledge Organization

The dominant North American classification and subject heading systems, the Dewey Decimal Classification and the Library of Congress systems, are not adept at representing Indigenous peoples and topics. These types of knowledge organization systems are shaped by culture and they reflect world view through the selection of terminology, concepts, and the ways in which they show or do not show relationships.^[70] The literature documents that the mainstream systems tend to marginalize, omit, or misrepresent Indigenous topics. These types of inaccuracies can occur through historicization, lack of specificity, lack of relevance, lack of recognition of sovereign nations, and the omission of the historical realities of colonization.^[71,72] Cataloging practice for Indigenous topics must recognize the names, relationships, places, histories, and concepts used by Indigenous peoples. If Indigenous perspectives are not incorporated into knowledge organization tools, it creates another barrier to access for Indigenous peoples at the same time as perpetuating inaccurate and culturally inappropriate representation for the

general public. From Indigenous perspectives, intellectual access to public collections in libraries, archives, and museums is important for educational and informational purposes, and also for claims research, genealogy, and the revitalization of traditions, languages, and histories.^[73] The dominant classification and subject heading systems are now used on a global scale, and while this enables unprecedented sharing of knowledge, it also has unprecedented power to marginalize Indigenous knowledge domains, and to establish the cultural perspectives of mainstream North America as a global norm.^[74] Ambitious national Indigenous thesaurus projects have been undertaken in both Australia and New Zealand to provide more balanced representation and access: the Māori subject headings provide access to the Māori body of knowledge held in public institutions for Māori people.^[75] The Australian Aboriginal and Torres Strait Islander Thesaurus aims to improve access to Aboriginal and Torres Strait Islander materials: “It is important that the Indigenous voices of Australia are heard and felt through proper representation in catalogues.”^[76] International bodies, such as, the UN and the International Federation of Library Associations and Institutions (IFLA), assert the importance of preserving Indigenous knowledge and protecting the individual and collective rights of Indigenous people.

Intellectual and Cultural Property (ICIP)

The concept of ICIP rights refers to past, present, and future tangible and intangible expressions of heritage. These expressions exist within a body of cultural practices, knowledge systems, and resources that serve to define cultural identity.^[77] The results of a global study of Indigenous heritage led by Professor Erica-Irene Daes, Chairperson of the UN Working Group on Indigenous Populations, is widely cited as a standard and it shaped The Declaration on the Rights of Indigenous Peoples^[78] which was adopted by the UN General Assembly on September 13, 2007. One of the most comprehensive statements on the individual and collective rights of Indigenous people, the Declaration states:

Indigenous peoples have the right to practice and revitalize their cultural traditions and customs. This includes the right to maintain, protect and develop the past, present and future manifestations of their cultures ... taken without their free and informed consent or in violation of their laws, traditions and customs.”^[79] When knowledge is removed from communities and the systems are disrupted, there is a community loss of control over ways they are represented and used. Some Indigenous legal concepts, such as, the notion of collective rights, do not easily fit into existing legal frameworks. Public institutions, such as libraries, archives and museums that hold Indigenous collections face a range of ICIP issues, such as, the retrospective identification of heritage materials; identification of the community of origin; the determination of copyright

and ownership; ascertaining restrictions on access.^[80] Because existing copyright law and intellectual property law do not wholly protect ICIP, protocols have been developed as guidelines for institutions and organizations to use in their interactions with Indigenous people.

Indigenous Protocols

Protocols are seen as a bridge between Indigenous customary law and existing legal instruments. Protocols guide practice, and are localized in order to reflect the approaches of specific communities and the contexts of each institution's mission and collections.^[81] *The Aboriginal and Torres Strait Islander Library and Information Resource Network (ATSILIRN) Protocols* are considered to be a leading guide for libraries. They serve as a compass for discussion, policy, and practice related to the care of Indigenous materials and to the development of relationships between Indigenous communities and individuals, and institutions. First published in 1995, the protocols were revised in 2005, and are considered to be living documents that are continuously updated.^[81] Some of the primary concerns regarding information issues from Indigenous perspectives are governance and policy, education and training, and increased Indigenous employment and staffing.^[82] In addition Indigenous peoples have concerns regarding community ownership and rights management, guidelines for access to sensitive or sacred knowledge, and ownership of oral traditions and songs.

Virtual Repatriation

Indigenous communities have had their knowledge systems disrupted in many ways. One significant outcome is that collecting institutions, such as museums, libraries, and archives throughout the world hold large collections of materials collected from or of significance to Indigenous people. Virtual repatriation is the process by which digital copies of objects, recordings, images, and documents are returned to the originating Indigenous community. In some cases virtual repatriation partnerships exist between Indigenous groups and collecting institutions, such as, the Smithsonian National Museum of the American Indian (NMAI) Spiral of Knowledge project. In other cases, Indigenous communities repatriate digital copies from collecting institutions or churches, or from individual collectors such as anthropologists, missionaries, and others. The returned digital materials gradually amass to form local Indigenous knowledge bases which in themselves may present significant IT issues, and ethical and knowledge organization challenges for the community.^[83] Frequently multidisciplinary in scope with various types of content and different file formats, these knowledge bases use software and hardware that are vulnerable to change. Systematic planning for data migration, attention

to standards compliance, and consideration of sustainability, interoperability, and portability issues are therefore required at the community level. Intellectual property and copyright guidelines, and digital rights management are increasingly important in these types of environment where the boundaries of collecting institutions are coalescing and technologies are converging. Collecting institutions meet their own ownership and access requirements in order to repatriate materials to communities, and Indigenous communities then face ongoing intellectual property issues related to both the returned materials and to contemporary materials. Communities may face a range of ICIP considerations, including different kinds rights for different types of knowledge and material formats; considerations for individual viewing, public viewing, and reproduction of materials by Indigenous people or external groups; and considerations regarding community members adding their own annotations to shared databases. The rights management systems utilized must satisfy Indigenous customary approaches, as well as national laws and institutional regulations. Dr. Martin Nakata suggests that coordinated approaches at the community level, the state level, or possibly national level may be beneficial as the number of knowledge bases and amount of content can only be expected to increase over time both within individual communities and among communities. The complexities of these virtual repatriation processes are beginning to constitute a specialist area of practice.^[84]

RESEARCH IN INDIGENOUS LIBRARIANSHIP

Indigenous scholars are asking new questions of research and creating an emergent scholarship that speaks to Indigenous interests in reclaiming languages, histories and knowledge, and creating new solutions to address the negative impacts of colonialism.^[85] These processes require (re)conceptualizing research as a transformative practice: capable of transforming the world and capable of transforming itself. Indigenous research methodology offers expanded systems of knowledge and ways of knowing that hold potential for sustainable research practices with global applicability in the twenty-first century.

Practitioners of Indigenous librarianship are positioned to take up the new methodologies of Indigenous theorists to inform research practice: there is a need for empirical, theoretical, evaluation, and policy research in Indigenous librarianship. In 1992 Cheryl Metoyer-Duran observed a lack of baseline data needed to conduct research in order to plan, develop, implement, or evaluate services in tribal communities. "At present, there is no comprehensive study which considers the definition of tribal libraries, their location, description of resources and services, staffing or clientele."^[86] This still holds true in 2008 and continues to impede the further development of planning,

preservation, and the dissemination and evaluation of services and collections.

The key issues for Indigenous librarianship highlighted in this entry suggest a range of areas for future research. Areas of applied research could include, best practices in Indigenous library development, Indigenous approaches to digitization, local and national information policy, literacy education, cultural and intellectual property rights, knowledge organization and representation, professional ethics and professional competencies. There is a need for further development of social justice, critical and Indigenous theoretical frameworks within library and information science. Linda Tuhiwai Smith's work on decolonizing methodologies could be used to provide a map of the terrain of research relationships: some research will be undertaken only by Indigenous researchers in Indigenous communities, other types of research will be controlled by Indigenous people with outside partners, and some will constitute a whole range of collaborative research partnerships with Indigenous people and others.^[87] A fundamental issue for research and for practice is the education of Indigenous librarians and education for Indigenous librarianship.

EDUCATION FOR INDIGENOUS LIBRARIANSHIP

Kelly Webster, past president of the American Indian Library Association (AILA) and a member of the Oneida Tribe of Indians of Wisconsin, recalls her experience in library school.

I went to library school in the mid-1990's, and like most other students I did not hear a word about library services to American Indians in my classes, meet another Native person in the program, or encounter anything in my assigned readings on the topic^[88]

Employment and education of Indigenous people across the library and information sector is repeatedly cited as a high priority in the United States, Canada, Aotearoa/New Zealand, and Australia. However, there has been limited success at recruitment and relevant curriculum development. The Association for Library and Information Science Education (ALISE) statistics on ALA accredited programs in the United States and Canada (2004) show full-time American Indian LIS faculty represented six positions (0.8%) of the faculty in 51 schools.^[89] In 2002–2003, only 26 American Indian graduates were awarded LIS degrees out of a total of 7284 graduates: there were no American Indian doctoral graduates.^[90] Part of the recruitment challenge hinges on the development of culturally relevant and responsive curriculum. The Knowledge River program at the School of Information Resources and Library Science (SIRLS), University of Arizona; the University of New Mexico, INLP; and Honoring Generations

at the University of Texas at Austin Information School are promising initiatives in education and recruitment of Indigenous people.^[91–93] The LIANZA statement of core competencies includes awareness of Indigenous knowledge paradigms and describes it in sufficient detail to guide to curriculum development by education providers.^[94]

There is a need to educate tribal librarians who can plan and implement infrastructure for twenty-first century community library and information services, and professionals who can design and manage Indigenous memory institutions, facilitate repatriation efforts, and navigate the complex relationships required to build alliances. At the same time, the broader profession and collecting institutions require education to address widespread issues of ignorance and misunderstandings that are a legacy of past educational failures. An example of staff professional development is modeled by the University of Queensland where Indigenous and non-Indigenous library staff have partnered on developing a staff education program about Indigenous issues and histories. This occurred within an organizational climate that has a Senate-approved mandate to improve Indigenous education by challenging preconceived ideas of knowledge creation, dissemination, and recognition.^[95]

PROFESSIONAL ASSOCIATIONS

From the seminal work of the National Indian Education Association with the American Library Association that produced the *Goals for Indian Library and Information Service* (1973) to the formation of the International Indigenous Librarians' Forum (IILF) in 1999, the initiatives of Indigenous peoples' associations guide the field. The following are key groups at national and international levels.

The IILF was formed in 1999 for Indigenous library, archives and information workers to share experiences and to discuss common issues and concerns. The IILF meets every 2 years and publishes conference proceedings on an irregular basis. The first forum was convened by the Māori in Auckland Aotearoa/New Zealand in November 1999. Subsequent forums have been hosted by local Indigenous groups in Jokmökk, Sweden in 2001; Santa Fe, New Mexico in 2003; Regina, Saskatchewan in 2005; Brisbane Australia 2007; Otaki in Aotearoa/New Zealand in 2009.

The AILA, founded in 1979 as a result of the 1978 White House Pre-Conference, has a mandate to improve library services to American Indians and Alaska Natives in school, public, and research libraries, both on- and off-reservation, and to disseminate information about American Indian and Alaska Native library issues. AILA holds meetings twice a year in conjunction with the American Library Association, runs an e-mail list that networks American Indian librarians and librarians serving American Indian communities, publishes a quarterly newsletter,

and has formed a classification and subject access committee that plays a leadership role in shaping culturally appropriate subject representation.

The Aboriginal and Torres Strait Islander Library and Information Resource Network (ATSILIRN) was established in 1993 to provide an information network and support for Aboriginal and Torres Strait Islander peoples working in libraries. The organization also includes members and institutions whose work addresses the information needs of Australian Indigenous peoples. ATSILIRN holds annual conferences and has participated in the development of protocols for libraries and archives serving Aboriginal and Torres Strait Islanders and the compilation of the Aboriginal and Torres Strait Islander Thesaurus.

In 1992, Māori library workers established a professional association, Te Rōpū Whakahau (TRW, the Māori Library and Information Workers' Association). Its goals are to provide cultural and professional support to Māori working in libraries, and to create a forum for Māori voices to inform policies and practices relating to the care of Māori material in libraries and archives. The TRW publishes a regular newsletter, makes policy submissions, participates in research projects, organizes *hui* (gatherings/conferences), and produces publications related to Māori library issues.

In addition, there are numerous professional associations at the local, state/provincial, and national levels within the United States, Canada, Australia, and Aotearoa/New Zealand that are involved with the development of Indigenous library and information services, and educating the general population about Indigenous issues, histories, and diverse approaches to knowledge and ways of knowing. At the international level, a proposal to form a Special Interest Group (SIG) on Indigenous knowledge was submitted to the International Federation of Libraries and Institutions Association (IFLA) at its annual conference in Quebec City (2008).

CONCLUSION

In the United States, Canada, Australia, and Aotearoa/New Zealand Indigenous librarianship is located within policy environments of Indigenous self-governance and national reconciliation. Two clear implications for librarianship are: (1) Indigenous information demands will continue to grow exponentially due to expanding Indigenous self-governance activities and the exigencies of demographics and (2) Indigenous library and information services can only succeed under the direction of Indigenous nations, or in ethical partnerships between Indigenous and non-Indigenous partners.^[96] The development of Indigenous libraries and information services is key for cultural revitalization and maintenance, and for the economic and educational interests of Indigenous communities and

individuals. At the same time rapidly growing young Indigenous populations can be expected to increase demands for youth programs, education, and bridging programs from public institutions.^[97] Equitable access to public institutions and infrastructure are necessary to avoid creating systemic two-tiered systems that will further marginalize an increasingly large proportion of national populations.

The scholarship of Indigenous librarianship has important contributions to make to library and information science as a discipline that speaks to real-world issues in local and global contexts. It has the potential to mobilize Indigenous knowledge to shape the theory and practice of the broader profession, including curriculum development and research in library and information science faculties. As Indigenous librarianship serves Indigenous interests, it also serves the education of all learners who are citizens of countries where Indigenous peoples are the First Peoples.

Abstract

A selection of representative definitions of information is drawn from information science and related disciplines and discussed and compared. Defining information remains such a contested project that any claim to present a unified, singular vision of the topic would be disingenuous. Seven categories of definitions are described: communicatory or semiotic, activity-based (i.e., information as event), propositional, structural, social, multi-type, and deconstructionist. The impact of Norbert Wiener and Claude Shannon is discussed, as well as the widespread influence of Karl Popper's ideas. The data–information–knowledge–wisdom continuum is also addressed.

The work of these authors are reviewed: Marcia J. Bates, Gregory Bateson, Paul Beynon-Davies, B.C. Brookes, Michael Buckland, Ian Cornelius, Ronald Day, Richard Derr, Brenda Dervin, Fred Dretske, Jason Farradane, Christopher Fox, Bernd Frohmann, Jonathan Furner, J.A. Goguen, Robert Losee, A.D. Madden, D.M. McKay, Doede Nauta, A.D. Pratt, Frederick Thompson.

INTRODUCTION

The concept “information” is of signal importance to all the information disciplines. Perhaps for that reason, it is a term that has been defined in countless ways over many decades. It would be fair to say that there is no widely agreed-upon definition or theoretical conception of the term. The meaning of this term is still highly contested. In this regard, the status of the term is similar to that of “communication” in the communication sciences.

In light of the lack of agreement about the definition of the term “information,” the main objective of this entry will be to lay out some of the major classes of definitions and theoretical constructions of the term that are currently or recently in play. No effort will be made to capture and discuss every definition that has been provided in the literature; rather, major types will be presented, as well as popular ideas that are recurrent in the literature. The discussion draws from writings over the last sixty years; the approach is by category rather than by chronology.

The effort to define information is active in other disciplines besides those explicitly concerned with the topic; philosophy, cognitive science, electrical engineering, computer science, and systems theory, among others, have been active players on this scene as well. The objective of this entry, however, is to concentrate on the ideas about information either that have been developed within the information disciplines or, in a few cases, that have come from other fields but have also been influential in the information disciplines. For coverage of other approaches to the concept, the reader is directed to reviews by Aspray,^[1] Belkin,^[2] Capurro and Hjørland,^[3] Cornelius,^[4] Furner,^[5] Meadow and Yuan,^[6] and Wersig,^[7]

A different way of acquainting oneself with the numerous issues and debates across the disciplines about information would be to examine several collections of articles written by authors bringing a variety of perspectives to the question. See Kornwachs and Jacoby,^[8] Davies and Gregersen,^[9] and Ibekwe-San Juan and Dousa.^[10] In the latter volume, Furner takes an amusing, but highly illustrative, approach by citing and discussing 18 papers across the disciplines—almost entirely not in information science—that have the title “What is information?” and that have appeared between 1955 and 2012.^[11]

Some authors embed a discussion of information within a much larger philosophical or theoretical program. In other words, exposition of the meaning of the term “information” is not a primary goal, but only incidental to much larger projects. It is beyond the focus of this article to attempt a review of these larger intellectual programs. Prime examples include Søren Brier's “cybersemiotics”,^[12] Benny Karpatschof's dissertation on “Human Activity”,^[13] Howard Resnikoff's analysis of information within a mathematical, physical, and signal detection framework,^[14] Jan Kåhre's “mathematical theory of information”,^[15] and separate disquisitions on the relationships among physics, biology, and information by Roederer^[16] and by Stonier.^[17–19] A recent book by Reading^[20] in the biosciences is intended to be broad, readable, and compact on the subject of information in those fields. Another author in this category is Luciano Floridi, a philosopher, who is developing and promoting an area of philosophy to be known as “philosophy of information.”^[21] He develops his own view of information as a philosopher, with attention to the issues of concern to that discipline in the article “Information,”^[22] as well as in a

short book.^[23] Floridi's recent book, *The 4th Revolution: How the Infosphere is Reshaping Human Reality*,^[24] has been reviewed scathingly by the philosopher John Searle, who comes from a distinctly different perspective on information.^[25]

Because Norbert Wiener's and Claude Shannon's ideas of information were so influential at the dawn of the "Information Age," their influence is discussed in a preamble in the following text. Shannon's actual "information theory," however, is reviewed elsewhere in an entry by that name in this encyclopedia.

After the preamble, conceptions of information of the following types will be reviewed in succession:

- Communicatory or semiotic
- Activity-based (i.e., information as event)
- Propositional
- Structural
- Social
- Multi-type
- Deconstructionist

Between these categories, we will take two interludes, one to discuss the "Problem of Popper's Worlds," regarding the philosopher Karl Popper, and the other to address "DIKW" or the commonly discussed sequence known as "data-information-knowledge-wisdom." Both of these, Popper's "three worlds" concept and the DIKW sequence, have motivated so much discussion in the information sciences around information that they merit separate discussion.

In the process, the work of the following people will be addressed: Marcia J. Bates, Gregory Bateson, Paul Beynon-Davies, B.C. Brookes, Michael Buckland, Ian Cornelius, Ronald Day, Richard Derr, Brenda Dervin, Fred Dretske, Jason Farradane, Christopher Fox, Bernd Frohmann, Jonathan Furner, J.A. Goguen, Robert Losee, A.D. Madden, D.M. McKay, Doede Nauta, A.D. Pratt, and Frederick Thompson.

In this entry, no summary conclusion is made about "the best" or "the truest" understanding of the concept of information. Rather, the purpose is to present the array of ideas flowing around this core concept in the information disciplines, so that the reader may become acquainted with the issues.

PREAMBLE: THE ROLES OF WIENER AND SHANNON

It is almost impossible to overestimate the impact of Claude Shannon's ideas about information on the (American) intellectual culture of the 1950s and 1960s. In that era, there was a tremendous amount of attention directed to the technical revolution(s) that had become possible with the development of computers, television, new

communication technologies, and a new way of thinking about information. This new way of thinking percolated out of the academic world into the society at large and imbued at a subconscious level the thinking of people who had no understanding of Shannon's ideas per se.

Today, many scholars write dismissively about the concept of information (see the last portion of this entry) and reject the earlier excitement around the "Information Age" and the "Information Society" as a love affair with a cold, technical, even militaristic conception of the technology-driven society.^[26] Indeed, Frank Webster, writing in this encyclopedia about the "Information Society," analyzes the term's many weaknesses and confusions, without seeming to recognize the positive value originally gained from the ideas carried by the concept. Shannon appears in Webster's discussion only in terms of the "deracinated" definition of information that arises out of Shannon's writing. Ironically, as we shall see, it was, in fact, the very fecund power of that deracinated definition of information—i.e., a concept of information as independent of meaning—that allowed an explosion of scientific and social development around information and its social and technical role.

The new conception of information that came with Shannon was so fundamental, so pervasive in science and engineering, that today's critics do not actually see *it as it was to people then*. The several streams of new thinking on information were startling, different, and stimulating, compared to prior understanding. I believe that the impact was so fundamental that an earlier generation can be forgiven for inventing ideas like the "Information Age," the "Information Society," and "Information Explosion." The consciousness of information was so new and changed so many established ideas that it really felt to the participants like a new age marked by the new awareness of information.

It is fashionable now to deride that earlier absorption with the new concepts, but we are *able* to deride these concepts only because we have so thoroughly absorbed the learning from that time that it feels easy to dismiss it in favor of newer ideas. The ever-present fact is that people both build on and react to what was present earlier in their lives. Today's critics are, of course, doing that too. This author is old enough to remember that earlier time, and I choose to present that era as I understood it, as a bit of a counter to the somewhat dismissive attitude toward it that is popular nowadays.

Boulding wrote about three levels of organization in life: 1) static structures; 2) clockwork, that is, the world of mechanics; and 3) thermostats, that is, control mechanisms that maintain a stable condition by responding to feedback from their environment.^[27] These three levels have some parallel in the development of science in the Western world—the medieval belief in a static world created by God, followed by the Newtonian discovery and analysis of dynamic processes, followed by the cybernetic understanding of the role of information in life processes.

The world of Newton and his epigones was one in which the theory of forces and impacts of recognizable regular, measurable change was developed. The quintessential model of the mechanical universe is that of billiard balls being hit and rolling into other balls and making them move in a certain direction with a certain force.

The movement of the planets was closely measured, the mathematics of change in the form of the calculus was developed, and a deep threat to the medieval concept of the static universe arose. The long history of religious controversy, with Galileo as a prime example and proceeding through the inquisition, the Reformation, and the Counter-Reformation, was in no small part due to the fundamental challenge offered by this new dynamic idea of how the universe worked.

In the twentieth century, information began to become important in the thinking of science and society. Problems of observation and the impact of observation emerged in early twentieth-century physics. Finally, during the 1940s and 1950s, the role of information was made theoretically explicit in the theory of cybernetics. The term came from a Greek root word meaning to govern or steer. Norbert Wiener's conception of cybernetics involved the governing of action through the feedback of information.^[28]

"Feedback" is a tediously trite term nowadays, usually employed in the context of customer relations or group therapy. But the idea behind it was revolutionary in Wiener's day. Wiener illustrated just how significant the idea was in his description of research that he conducted with a physician on physiological processes.^[29] Again, grossly simplifying, the thinking in that day in physiology was that when I reach out to pick up a pencil, this process is achieved by my brain sending a signal to muscles and tendons along the lines of "go get it," and the machinery of my arm goes into action and picks up the pencil. This was a classically mechanical concept of my actions. A pulse goes out to my arm to do a certain thing, I act, and then the pulse diminishes.

Wiener and his colleague demonstrated that the process did not work that way. Instead, when I start to pick up the pencil, I extend my arm in the direction of the pencil, and then, *utilizing constant kinesthetic and visual feedback*, I micro-adjust the position of my arm repeatedly and successively until it successfully lands on the pencil, grasps it, and picks it up. Picking up the pencil is not a single, mechanical, act, but rather an extended behavior utilizing continuous information feedback telling me whether my hand is on or off course and, if off course, enabling me to adjust the tension in muscles and the direction of my reach so that I can successfully touch and pick up the pencil.^[30]

Thus, in cybernetic situations, two processes are going on continuously in parallel—the physical forces and the detection and utilization of information about the physical forces, information that is used to affect the physical actions. While the billiard ball model was the one commonly used for the mechanical understanding of the

universe, with the impact of cybernetic thinking, the household thermostat became the standard model of cybernetics and feedback. In the summer heat, I set the thermostat for a certain temperature. When the heat in the room affects a sensing mechanism in the thermostat beyond a certain point, the air conditioning starts, and cools the room down to where the sensing mechanism again achieves its desired temperature, and the air conditioning shuts off. The sensing mechanism provides continuous information, and the design of the thermostat is such that when the information indicates that the room temperature is outside a desired range, the air conditioning comes on. Governing, or steering, is about utilizing information feedback to direct the ship of action.

In the larger history of scientific thinking, the development of cybernetics drew attention to the *distinct role of information* in physical and social processes. Previously, the kinesthetic and visual feedback I get while picking up the pencil—as well as in countless other information-based processes—had been almost entirely invisible in the thinking of science. This may be one reason why the 1950s and 1960s were so obsessed with information—the role of information had at last emerged as a focal topic of interest in science; its role in influencing physical and social processes at last came to the fore and, once seen, was studied with fascination in many domains of science.

So what was Claude Shannon's role in all this scientific development? Shannon and Wiener worked on some of the same ideas during this fertile period. Shannon, working at Bell Laboratories, however, developed the mathematical and engineering theory to put an understanding of information on a firm basis.^[31] Strictly speaking, Shannon did not define information at all, at least in any conventionally understandable way. Shannon found a way to measure the *amount* of information going over a transmission channel. As Wiener puts it, "...we had to develop a statistical theory of the *amount of information*, in which the unit amount of information was that transmitted as a single decision between equally probable alternatives."^[32]

Since the alternative messages, letters, words, or other units of communication are not always sent with equal probability, the formula Shannon developed measured the amount of information as a function of two things—the number of alternatives out of which a message might be selected for sending and the probabilities of the various messages. The more possible messages from which the sent message is selected and the more equiprobable the messages, the greater the amount of information transmitted.

Shannon's analysis was revolutionary in several senses. Before him, engineers really did not have a means of computing the maximum amount of information that could be transmitted through a channel of a given size or configuration. It was assumed that it would be possible to go on improving channels to carry more and more information. Shannon's formulas enable the calculation of the

maximum possible information transmission for a given physical configuration.

Once Shannon developed a firm model of the amount of information, actual and possible, in a channel, he could clarify the role of redundancy, of error rates, and noise in a channel. For example, since the letters of the alphabet do not appear in written text with equal probabilities, the amount of information conveyed with English text is well less than 100% of the amount of information that could be conveyed if each letter were equiprobable. Further, Shannon mathematically analyzed the role of noise in a channel and the ways in which redundancy could compensate for the noise. These discoveries were immensely important for all sorts of communication engineering situations. Go to the right section of an engineering library, and you can find textbooks full of hundreds of mathematical formulas developed out of these crucial insights by Shannon. Shannon's work revolutionized communication engineering. His key paper has been cited over 7000 times in the ISI "Web of Science" database.^[33]

His impact went well beyond engineering, however. It was as if for the first time people saw the informational regularities beneath the surface variety of the text sent over a wire or the words spoken on the telephone or written in a book. Shannon's model of information is dismissed today because he separated information from meaning. What is currently forgotten, however, is that this separation was in fact an *achievement*. People had not been able to make that differentiation before. Now, with far greater clarity and understanding, the handling of information in quantitative terms at last came into its own. In 1951, the psychologist and linguist George Miller wrote the book *Language and Communication*, which essentially consisted of working out the implications of Shannon's work for those disciplines.^[34] In the process, Miller educated a generation of social scientists on this way of thinking.

The fundamental clarification of the relationship between messages and the amount of information they convey (Shannon) and the concomitant recognition of the important role of information throughout life processes (Wiener) led to an enormous surge of research and theorizing throughout science about information. (Other researchers, such as John von Neumann and Oskar Morgenstern, had important roles as well.) Just as those hundreds of mathematical formulas had to be worked out in the engineering world, so also did the social sciences need to work with these same ideas and transform some parts of those disciplines.

The application of Shannon's approach to the social and behavioral sciences was not straightforward, however. There were many insights gained, but many problems encountered as well. After a while, the initial enthusiasm in the social sciences waned—to the point where it is now fashionable to deride these post-War ideas. But we are shaped by those ideas so thoroughly nonetheless that we can only attempt to throw off their influence.

COMMUNICATORY OR SEMIOTIC DEFINITIONS OF INFORMATION

We begin with definitions/conceptions of information that are framed within a communicatory or signaling context. Some authors even take the approach to the point of identifying meaning with information.

A.D. Madden

As a recent example, in 2000 Madden defined information as "a stimulus originating in one system that affects the interpretation by another system of either the second system's relationship to the first or of the relationship the two systems share with a given environment. . . ."^[35] In 2004, he simplified it to "a stimulus which expands or amends the World View of the informed."^[36] The latter definition is reminiscent of Boulding's concept of the "image," which is the grand total of my (or any individual's) subjective knowledge, my mental image of the world, and my place in it.^[37] Boulding argued that behavior depends on this image. So in Madden's approach, information is, in effect, something that alters the image.

Gregory Bateson

Gregory Bateson applied concepts of information and feedback to the psychodynamics of human relations, most famously writing of the pathological, feedback-based, "Double Bind" relationship.^[38] He also wrote about information science. Expressing the semiotic approach still more generally, Bateson said that information is a difference that makes a difference.^[39] This approach has its roots in the idea of the single difference being the elementary unit of amount of information, the single bit, the zero or one. The difference that makes a difference, presumably, makes that difference to a sensing being.

B.C. Brookes

Brookes, one of the grand old men of British information science, took a similar tack. The following is his "fundamental equation" for the relationship between information and knowledge:

$K[S] + \Delta I = K[S + \Delta S]$, which states in its very general way that the knowledge structure $K[S]$ is changed to the new modified structure $K[S + \Delta S]$ by the information ΔI , the ΔS indicating the effect of the modification.^[40]

Thus the (human) knowledge structure in the mind is changed in some way with the input of information.

Doede Nauta

Nauta takes information quite explicitly to be meaning but in a particular sense. "Information is that which is

common to all representations that are synonymous to the interpreter (synonymity is identity of meaning).”^[41] Thus, information is the meaning that is common to all the different ways of expressing that meaning. Here, it would seem that only representations can contain redundancies, because information is the common meaning core to all the different possible representations. In this approach, Nauta drew on both semiotic and (Shannon) information theoretic approaches.

Robert Losee

Losee developed what he calls a “discipline-independent definition” of information. “Information is produced by all processes and it is the values in the characteristics of the processes’ output that are information.”^[42]

Information is always informative about something, being a component of the output or result of the process. This ‘aboutness’ or representation is the result of a process or function producing the representation of the input, which might, in turn, be the output of another function and represent its input, and so forth.^[43]

Losee takes as his central example the baking of a cake. “Examining the cake provides information about both the process and the original ingredients. . . . The choice of high quality ingredients. . . . will affect the outcome. . . . Varying the process, such as the amount of time in the oven. . . . also changes the final product...”^[43]

This definition raises a couple of questions. First, what about situations that are not processes? Can there be no information there? Or is process so universal that everything is a result of it?

Second, it is with cake baking, as with many physical processes, that the information produced from the process is often quite incomplete and can be misleading. Losee says that examining the cake provides information both about process and original ingredients. But, in fact, the person who had never seen a cake before almost certainly would not know enough to be able to figure out from the output alone all that went into making it, both in ingredients and processes. This is true with many processes. Often, there is an emergent result—yeast does things in the cake not in evidence when the baking begins. The baking causes chemical processes that lead to the final result being very different in qualities from the starting dough.

Thus, in the experience of human observers, information can be limited and distorted coming out of a process, and it can be also be quite unambiguous and complete, as when we know of the process “add +1 to the output of prior process.” In the latter case, the information we derive from the result is presumably complete and correct. Thus, it would appear that Losee’s general formulation of information includes many situations where the information is

limited or distorted, as well as situations where the information resulting from a process is unambiguously clear.

INFORMATION AS EVENT

Allan Pratt

Pratt provided probably the most developed version of a conception of information in which information is an *event*, that is, he looks at the process of being informed and derives the term “information” from that. Pratt, too, draws on Boulding’s concept of “the image.” He says: “My Image of the world, and my relationships in it, which includes my perception of cause and effect, of time, of space, of values, of everything which impinges on my consciousness, is different from yours, and from that of every other person in the world.”^[44]

After a person has received and understood the content of a message, in ordinary speech we say that he has become informed about the matter at hand. This is a surprisingly precise and accurate statement. He has been ‘in-formed.’ He has been inwardly shaped or formed; his Image has been altered or affected.

In-formation is the alteration of the Image which occurs when it receives a message. Information is thus an event; an event which occurs at some unique point in time and space, to some particular individual.^[45]

He compares the concept “information” to the concept “explosion.” “Every explosion is unique; no two are identical.” “Further, explosions cannot be stored or retrieved. One may, of course, store and retrieve potentially explosive substances. . . .” Later, he admits: “informative event” may be a more felicitous term than “an ‘information’.”^[45] Here he comes upon the practical problem of the mass-noun usage of the word “information”; “an information” as a count noun just does not fit into English usage.

PROPOSITIONAL DEFINITIONS OF INFORMATION

Propositional definitions are ones in which a piece of information is considered to be a claim about the world, a proposition.

Richard Derr

Perhaps the most accessible such definition is that of Derr: “. . . information is an abstract, meaningful representation of determinations which have been made of objects.” “A determination is a judgment of what is the case.”^[46] Using

the example of an ordinary sentence, he elaborates as follows:

Five necessary conditions of the truth of the first sentence have been identified. In order for Sentence 1 to be true, it is necessary that

1. information be a representation,
2. the representation be abstract,
3. the representation be meaningful,
4. the representation consists of determinations which have been made,
5. the determinations have been made of certain objects.^[46]

Derr states that “[n]one of these conditions by itself is sufficient to insure the truth of this sentence; however, jointly, they constitute a set of sufficient conditions.”^[46] He goes on to argue that, based on these five essential properties, four derivative properties of information can be identified as well: Information is *communicable*, *informing*, *empowering*, that is, one can take action based on having the information, and *quantitative*, that is, information varies in amount.^[47]

Fred Dretske

Dretske, a philosopher, has been widely influential in his conceptualization of information. He draws heavily on the Shannon conception of information. Much of his book is taken up with working through the logical and philosophical implications of his position, and no attempt will be made to expatiate that here. Instead, let us take his simpler, introductory description of information:

Roughly speaking, information is that commodity capable of yielding knowledge, and what information a signal carries is what we can learn from it. If everything I say to you is false, then I have given you no information. At least I have given you no information of the kind I purported to be giving.^[48]

Later, “Information is what is capable of yielding knowledge, and since knowledge requires truth, information requires it also.”^[49] Thus, to be information, a proposition must be true. Dretske takes his analysis through many complex arguments, but at the heart of every argument is the core statement “s is F.” The latter is the generic statement of a proposition, a claim.

He distinguishes information from meaning in the following way. A sentence, such as “Joe is at the office,” has a meaning that arises straightforwardly from interpreting the sentence for anyone literate in English. A sentence may, however, carry much more information as well, beyond the meaning of the sentence itself. “The acoustic signal that tells us someone is at our door carries not only the information that someone is at the door, but also the

information that the door button is depressed, that electricity is flowing through the doorbell circuit, that the clapper on the doorbell is vibrating, and much else besides.”^[50] Thus, Dretske’s sense of information includes all the demonstrable implications of a proposition, not only the (more limited) meaning of the proposition itself.

Christopher Fox

Fox takes his propositional view of information through many transformations as well. Again, using the simplest formulation for our discussion here, Fox is essentially claiming that the information (if any) contained in a set of sentences in a particular context is the proposition p such that, first, p is the conglomerate proposition expressed by the set of sentences in that particular context and, second, that the agent of that context is in a position to know that p.^[51] Put still more colloquially, information is the collective propositional claim of a set of statements in a given context, provided the agent in that context is in a position to know that p.

Fox titles his book *Information and Misinformation* and spends some time analyzing the latter concept as well. He disagrees with Dretske in that he does not feel that the act of “informing” necessarily means informing someone of a *true* proposition. He concludes, through a series of arguments based on the logical and linguistic character of true and false statements, that *informing* does not require truth, that is, the claim “that p” need not be true for someone to be informed of it. He argues, however, that we use “misinform” in a stronger sense—that to misinform someone necessarily means that the person is being informed of something that is not true. So we *inform* people of things that may or may not be true, but when we *misinform* someone, it necessarily involves telling the person something that is not true.^[52]

We are now in a position to return to Losee’s conception of information. Losee’s position admits of misinformation too. He says, “The value of a variable is information about the input; when the information is only partial and is tainted by error, it is better understood as misinformation. Essentially, this is information that is partly or wholly false.”^[53] So in Losee’s conception, the value produced by a process may indeed be inadequate or inaccurate and should then be known as misinformation.

STRUCTURAL DEFINITIONS

In addition to Frederick Thompson, discussed in the following section, we will review two other authors whose definitions are largely structural, D.M. MacKay and Marcia Bates. Their definitions are “multi-type,” however, and will be reviewed in the section on multi-type definitions.

Frederick Thompson

Thompson makes a discursive argument about information as a kind of structure. He recognizes the ways in which the structuring and organizing of information contains its own information, and is therefore likewise informative. He describes information as “a product that results from applying the processes of organization to the raw material of experience, much like steel is obtained from iron ore.”^[54] He also compares the scientist to the artist in that “[d]ata are to the scientist like the colors on the palette of the painter. It is by the artistry of his theories that we are informed. It is the organization that is the information.”^[55]

Commonly, in daily life, the forms of organization of information are seen to be neutral, content-free. Indeed, they are often taken for granted and not even noticed. Thompson brings out the ways in which these organizing activities are themselves content, influencing, to a greater or lesser extent, the overall meaning of the text or other body of information. This is an intellectual position—highlighting the impacts of the form and organization of information—that has been taken up by many more recent scholars, for example, Geoffrey Bowker and Leigh Star.^[56]

SOCIAL DEFINITIONS

The definitions considered to this point are drawn largely from logical and scientific points of view. This is sometimes known as a *nomothetic* approach; the fundamental effort in the sciences is to discover causes, effects, patterns, and tendencies that underlie the surface variety and particularity of life. The humanities perspective of valuing and studying the unique, specific characteristics of a situation, social group, or event, known as an *idiographic* approach, has not yet been represented here. In fact, probably due to the influence of the post–World War II scientific interest in information, many people coming from a humanities point of view have dismissed “information” as a specifically technological and heartless concept to be perennially contrasted with the rich detail of specific institutions and historical moments, such as a study of the library in nineteenth-century Illinois. However, the authors discussed in this section do embrace the concept of information, but argue that it must be seen as embedded in a social context.

Ian Cornelius

In 1996, Ian Cornelius wrote about an “interpretive viewpoint” to information. Taking the practice of law for his example, he argued that information should be seen as socially constructed within a set of practices. A practice is a “coherent set of actions and beliefs which we conform

to along with the other people in our practice (whatever it may be, profession or game), and it has its own internal logic and ethic.”^[57]

My claim is that information is properly seen not as an objective independent entity as part of a ‘real world,’ but that it is a human artefact, constructed and reconstructed within social situations. As in law, every bit of information is only information when understood within its own cultural packaging which allows us to interpret it.^[58]

Further,

...[T]here is no separate entity of information to discover independent of our practices. Up to the point that it is sought by a practitioner within a practice it is not information and cannot be interpreted.

When a practice is seeking to impose meaning on something, that thing will already have come within the interpretive range of that practice and will already be at an early stage in a process of interpretation.^[59]

Thus, information must be seen within the dense context of social relations, negotiations, and understandings operative in a particular social context. Cornelius compares the embeddedness of information received and interpreted with the embeddedness of most interpretations of the law.

Joseph Goguen

Writing a year later, Joseph Goguen developed a more detailed conception of a socially embedded information.^[60] His more idiographic approach may have succeeded in humanizing and detechnologizing the concept for those of a more social science or humanities bent. He defines information as follows: “An item of information is an interpretation of a configuration of signs for which members of some social group are accountable.”^[61]

He argues that all information is situated within a context and can only be fully understood within that context. He then addresses the question of whether any information is ever context-free; is some information more bound within a specific context than other information is? He describes a continuum of the character of information, from “wet” to “dry.” He states that processes of abstraction and formalization are attempts to take information out of contexts and make it as generally applicable as possible. The more decontextualized, the “drier” the information.^[62]

Certainly, many scientific results fit this description. We do not need to know the specific circumstances in which Robert Boyle discovered Boyle’s law (physics) in order to gain full value from the use of Boyle’s law. On the other hand, enormous amounts of contextual knowledge is needed in order properly to interpret the reasoning

and strategy involved in directing the prosecution of World War II or, in the information system design context, the hostile attitudes toward use of an information system in a particular government agency.

According to Goguen

In general, information cannot be fully context sensitive (for then it could only be understood when and where it is produced) nor fully context insensitive (for then it could be understood by anyone in any time and place).

According to our social theory of information, meaning is an ongoing achievement of some social group; it takes *work* to interpret configurations of signs, and this work necessarily occurs in some particular context, including a particular time, place, and group. The meaning of an item of information consists of the relations of accountability that are attached to it in that context, and . . . the narratives in which it is embedded.^[63]

He draws on ethnomethodology for the *principle of accountability*: “Members are held accountable for certain actions by their social groups; exactly those actions are the ones constructed as socially significant by those groups.”^[64]

It should be understood that Goguen is developing this concept of information in the context of information system design and usability testing. He refers to the numerous instances where massively expensive information systems were abandoned because they were dysfunctional for the organization for which they were designed. He argues that the close observation of people as called for in ethnomethodology is the gold standard for learning how a group organizes the work of their institution—what systems of categories, what contrasts, what relationships matter to the group, and how the group divides up the processes and objects in their world in order to carry out their ongoing activities. Goguen: “In particular, ethnomethodology looks at the *categories* and *methods* members use to render their actions intelligible to one another; this contrasts with presupposing that the categories and methods of the analyst are necessarily superior to those of members.”^[64]

This is a powerful conceptualization of information that incorporates its social role. Goguen argues that information, as understood through his construction of the term, is *situated, local, emergent, contingent, embodied, vague, and open*.^[63] Recall Derr’s characterization of information and compare it to Goguen’s view: “abstract, meaningful representation of determinations which have been made of objects.”^[46] The idiographic and nomothetic world views are on display in this contrast. For my part, they both carry a lot of truth. I do not see that one or the other approach has to “win” in the culture wars. By incorporating both approaches in our thinking, we may end up with the richest possible understanding.

FIRST INTERLUDE: THE PROBLEM OF POPPER’S WORLDS

We interrupt this recital of different approaches to the concept of information in order to consider the role of the work of Karl Popper, a well-known twentieth-century philosopher of science, in discussions of the nature of information. Popper was not himself interested in the concept of information and used the word very little. However, he developed another idea, of three worlds in the scientist’s life, which has had enormous impact in information science and recurs again and again through the literature on information. Popper wrote over a number of years about what he called three “worlds”: “We can call the physical world ‘world 1,’ the world of our conscious experiences ‘world 2,’ and the world of the logical *contents* of books, libraries, computer memories, and suchlike ‘world 3’” (his italics).^[65]

It was important to Popper to distinguish one person’s subjective understanding of a scientific topic from a more objective existence of knowledge of science that is independent of individual people. Once Robert Boyle died, the knowledge of “Boyle’s law” did not die with him. It was expressed and recorded in the literature of science and was in the minds of many people who studied science. In short, scientific learning has a public, independent, and thus reasonably objective existence apart from any one person’s subjective understanding of a scientific finding.

It is the daily bread of the work of people in the information disciplines to address the recorded, “exosomatic” (outside the body) forms of information. When a philosopher writes about objective knowledge, argues for its importance, and is at pains to distinguish it from other “worlds,” it may seem that at last someone from outside the information disciplines has paid recorded knowledge the attention that it deserves. At last, the very heart of the work of information managers has been recognized and validated as a key part of science!

Unfortunately, however, a close reading of Popper indicates that he did not view information resources in the way that information professionals do. Though he would sometimes refer to objective knowledge in books and journals, thus making it easy to conflate the “thingness” of books in with the objective nature of scientific findings, in fact, it is evident again and again in Popper’s writing that when he is speaking of the objective nature of world 3, he means, as his definition earlier indicates, the *logical contents* of the books and journals, not the objects themselves. When he pays attention to the books themselves, he always calls them a part of world 1. Indeed, the scientific examples he uses are generally of the very “driest” sort, in Goguen’s terms—generally mathematical and physical examples. To make his point about objective science, he is determined to select examples that can live independently in the most unambiguous way from individual knowers.

Popper was a philosopher of science and was concerned about various debates he was having with his philosopher colleagues. It was important to him to argue for the idea that the body of scientific learning can be thought of as independent from any one individual's (world 2) experience. He called this "epistemology without a knowing subject."^[66] A prime argument of his was that we can learn more about epistemological issues associated with science if we attend to the world 3 form of science, rather than to questions of how an individual person comes to know and believe something, the traditional subject matter of philosophical epistemology.

But it appears that he was not particularly conscious of the contents of libraries as a domain of study or professional practice. Indeed, Popper appears to have been unaware of John Ziman's book: *Public Knowledge: An Essay Concerning The Social Dimension of Science*, published in 1968, which took a more socially sophisticated look at the senses in which science has a public existence.^[67] Popper was not a social scientist, and he rather ignored distinctions that would be important in the social sciences. He saw libraries as the abode of the logical content, but it was only the logical content that interested him—not the vast infrastructure of information institutions, professional associations, and laboratories supporting these exosomatic forms of information storage. In fairness to Popper, it was the philosophical, not the social or professional dimensions of the material aspects of science that interested him.

Nonetheless, Popper has held a continuing fascination for information studies, and discussion of his three worlds appears in the work of many, including Brookes,^[68] Rudd,^[69] Neill,^[70,71] Capurro and Hjørland,^[3] and other information scientists' work. It is not my objective here to analyze these appearances of Popper in information studies, except to say that Popper is often misunderstood, or the subtle distinctions he made are ignored. To take just one example, Capurro and Hjørland define Popper's world 3 as follows: "intellectual contents such as books, documents, scientific theories, etc."^[72] Treating scientific theories as being in the same category as books and documents, thus conflating world 1 with world 3, misunderstands Popper in a fundamental way. Again, scientific knowledge has a public and objective existence (world 3), apart from either an individual's subjective knowledge of science (world 2) or the physical embodiment of that knowledge in texts and documents (world 1). Scientific knowledge is objective not just because it is recorded in objects called books or disks. Popper's third world is different from the librarian's sense of recorded information existing in physical objects or electronic networks.

If the reader finds tackling the large body of writings by Popper to be daunting, J.W. Grove^[73] provides a good, knowledgeable discussion of world 3. The best places to find Popper's own discussions of world 3 are in his book

Objective Knowledge^[74] and in Chapter P2 of Popper and Eccles' *The Self and Its Brain*.^[75]

MULTI-TYPE INFORMATION DEFINITIONS

Donald MacKay

Donald MacKay, writing at about the same time as Thompson, who was reviewed previously, also saw information structurally, specifically, "Information: that which determines form."^[76] MacKay took a more rigorous scientific approach to conceptualizing information than Thompson did. Elsewhere, he defines it as "that which adds to a representation."^[77] Within this general formulation, three senses of information are distinguished:

1. Structural information content, measured by "logons"
2. Metrical information content, measured by "metrons"
3. Selective information content, measured by "bits"

MacKay divided the three measures mentioned earlier into two types, constructive and selective. The first two measures are labeled "constructive." The third measure, "bits," corresponds to Shannon-type information and is labeled "selective." Since the Shannon approach measures amount of information, in part, by the number of options from which a message is selected—a message chosen from 100 possible equiprobable messages is more informative than a message selected from 10 possible equiprobable messages—the amount is measured in an indirect way, in terms of the number of messages *not* sent, hence "selective."

It is interesting, therefore, to contemplate MacKay's effort to measure information in a more direct, or positive, way, with his first two "constructive" measures, logons and metrons. The logons he sees as "[t]he number of *distinguishable groups or clusters* in a representation. . . its *dimensionality or number of degrees of freedom*"^[78] The metron, on the other hand, is "that which supplies one element for a pattern." Later, "Thus the amount of metrical information in a pattern measures the *weight of evidence* to which it is equivalent."^[79] This approach is redolent of inferential statistics, though it appears to have been intended to be still more general than that. Whatever the case, it does not appear to have caught on as a general means of measuring information.

Brenda Dervin

Brenda Dervin developed an Information^[1-3] formulation of information, drawing heavily on the work of Richard Carter, though the distinctions she makes bear some resemblance to Popper's. (Carter's works were notoriously fugitive, seldom appearing in conventional publication venues.)

Dervin states: “In the most general sense, Information¹ refers to external reality; Information² refers to internal reality.” This distinction “forces our attention to the notion that information can be whatever an individual finds ‘informing.’ It moves our attention away from ‘objective’ information, toward assessing the ‘cognitive maps or pictures’ of an individual.”^[80] She then asks how the individual moves between these two realities. “How does he impose sense on reality when he finds none there?”^[81]

She argues that “[b]oth an individual’s selection and use of Information,^[1] and his creation of Information^[2] result from some kind of behavior. It is suggested here that these behaviors are in themselves legitimate informational inputs: Information.”^[3,81] In other words, Dervin sees Information^[3] as all the ways in which people make sense of their worlds, the set of techniques they have to make this reconciliation between internal and external worlds. She then provides examples of different ways that people make sense of their experiences: by “decisioning,” by using a “liking–disliking procedure,” by a “relating to others” strategy, that is, getting advice from others. In sum, we can say that in Dervin’s terms, Information^[1] is the external world, Information^[2] is the internal world, and Information^[3] is the procedures used to reconcile these two worlds.

Michael Buckland

Buckland argues for three types of information:

1. Information-as-process: “When someone is informed, what they know is changed.” This definition is similar to Pratt’s concept of “in-formation” (see “Allan Pratt” under “Information as Event”).
2. Information-as-knowledge: “‘Information’ is also used to denote that which is perceived in ‘information-as-process’”
3. Information-as-thing: “The term ‘information’ is also used attributively for objects, such as data and documents that are referred to as ‘information’ because they are regarded as being informative. . . .”^[82]

Buckland titled his article “Information as thing” and addresses this sense of information the most in the article’s discussion. He sees the information disciplines as primarily being concerned with information in this sense. “. . . [T]he means provided, what is handled and operated upon, what is stored and retrieved, is physical information (information-as-thing).”^[83] In this regard, his thinking most resembles that of Jason Farradane, who defined information as a “physical surrogate of knowledge.”^[84] Farradane argued that such a tangible concept was needed in order to develop a proper science out of information science.

Citing examples of documents, statistical data, statutes, photographs, etc., Buckland says, “In each case it is

reasonable to view information-as-thing as *evidence*, though without implying that what was read, viewed, listened to, or otherwise perceived or observed was necessarily accurate, useful, or even pertinent to the user’s purposes.” Later, “If something cannot be viewed as having the characteristics of evidence, then it is difficult to see how it could be regarded as information.”^[85] This characterization does leave the reader wondering if Buckland always distinguishes information-as-knowledge from information-as-thing. Suppose a legal precedent is considered evidence. Is the physical book where the precedent is published the evidence, or is it the “information-as-knowledge” within the book that is the evidence? It would seem to be important to distinguish the physical form of the record from its logical content.

Buckland goes on to say that most anything can be informative; therefore information is everything. “We conclude that *we are unable to say confidently of anything that it could not be information.*”^[86]

Buckland concludes by suggesting areas in information science where distinguishing “information-as-thing” could be helpful. He notes that historical bibliography, the study of books as physical objects, and statistical analysis of information objects (now known as “informetrics”) are areas where information-as-thing has primacy. Second, in the professional activity of the information disciplines, an understanding of the physical handling of different kinds of objects and materials is vital to the effective management of those resources.

Marcia J. Bates

Marcia Bates sets out self-consciously to build a conception of information that is suitable and productive for the information disciplines to use in theory and practice.^[87,88]

Her basic definition is a structural one—arguably the most suitable approach for disciplines concerned with material storage and access to information: “Information is the pattern of organization of matter and energy.”^[89]

She aligns with Wiener on the nature of information: Wiener has said, “Information is information, not matter or energy.”^[90] That is, she argues that information is not identical to the physical material that composes it; rather information is the *pattern of organization* of that material, not the material itself. (This contrasts with Buckland’s conclusion that information is everything.)

On the other hand, though the material world is indisputably materially “there” and not a figment of solipsistic imagination, how living beings perceive and conceive of that pattern of organization is immensely variable across species and across individuals and across the same individual at different times. In this sense, information may be both objective (called “information 1”) and subjective (called “information 2”—pattern of organization of matter and energy given meaning by a living thing). Thus, nature has a physical reality independent of human beings, in

which we can posit the existence of patterns of organization, even if we perceive them poorly or not at all, while living beings experience patterns of organization in their lives that may be uniquely their own, either as a species or an individual.

At the same time, she addresses information in the larger context of the development of life on earth, drawing on a conception developed by Susantha Goonatilake of the evolution of information transfer over the history of life on earth. Goonatilake's view of the broad fundamental channels of information is well suited to the needs of the information disciplines.^[91]

He argues that over the history of life on earth, information has been stored and transmitted in three fundamental ways: genetically, neural-culturally, and exosomatically, that is, through the genome, through cultural transmission, and through storage devices external to the body, such as stelae, scrolls, books, photos, and videos. Animals moved beyond just genetic information transfer to neural-cultural information transfer when they began to teach their young to hunt and otherwise survive as adults. Humans took neural-cultural information still further when they developed language and began memorizing and telling stories to pass on culture through the neural-cultural channel. Humans then developed an explosively growing capacity for exosomatic storage and transmission once they began to carve, draw, and write on more or less durable surfaces.

In developing her conception of information, Bates argues that in living organisms, information tends to move back and forth between encoded and embodied forms. Genetic information is encoded in the genome and embodied in the living animal, the phenotype. The phenotype, in turn, encodes the genome in reproductive material to the next generation. Neural-cultural information is encoded in the brain of an animal and embodied in the experiences, actions, and communications of the animal, respectively, called experienced information, enacted information, and expressed information. Exosomatic information is encoded in the external materials in which it is stored, whence it is again embodied in human experience during reading, touching, or observing.

It is the exosomatic information that is of greatest interest in the managerial practice of the information disciplines. Types of exosomatic information include embedded and recorded information. Embedded information comes from the enduring effects of animals on the earth—from a path beaten through the woods to deliberately fashioned tools, homes, and other objects. For example, a ceramic storage vessel dating from Roman times contains embedded information in its design, in any painting on it, in any residue of its contents, etc. These aspects were generally not designed for intentional communication with later generations; but we can discern many informative things from examining them. Recorded information is communicatory or memorial

information preserved in a durable medium. This type of information is the prime domain of most of the information disciplines—librarianship, archival science, knowledge management, etc.

To Goonatilake's three channels of information transmission, she adds a fourth channel, "Residue." Residue is the flow line of extinction, where previously encoded or embodied information degrades, as in the Biblical "dust to dust." This flow line is important in the information disciplines, because relatively durable information storage does not endure forever and can degrade to the point where no socially meaningful evidence remains.

Thus, in parallel to Goonatilake's three flow lines, Bates defined the following forms of information:

- The genetic flow line is associated with genetic information.
- The neural-cultural flow line is associated with experienced information (in the mind), enacted information (actions in the world), and expressed information (nondurable communications).
- The exosomatic flow line is associated with embedded information and recorded information.
- Finally, residue is associated with trace information—the pattern of organization of the residue that is incidental to living processes or which remains after living processes are finished with it. The importance of trace information to the archaeological and museum worlds is self-evident.

Bates argues for the value of such an approach by describing several example applications of these multi-type terms for information in information studies. For example, the study of information seeking behavior needs to incorporate an awareness of *all* the forms of information a person takes in:

People get information not just from paper sources, not just from other people, but also from the physical layout of their workspaces, from the design, not just the content, of informational genres, and above all, from the interaction of these various factors in a real situation. All the patterns of organization of matter and energy—cognitive, physical, architectural, social, linguistic—are informative.^[92]

Thus, all types and forms of information need to be incorporated in our thinking in doing information research, and having these multiple types of information in mind can promote that awareness and use in research and teaching throughout the information professions.

Paul Beynon-Davies

Beynon-Davies comes at information from the perspective of the information systems discipline. "Significance" is his

core concept, rather than information.^[93,94] What he calls “the enactment of significance” consists in three levels of systems—data, information, and activity. These are called, respectively, forma, informa, and performa. Core to these three concepts are the ideas of representation, communication, and performance. Thus, a system of representation may be the ones and zeroes of a computer operating system or the alphabet. Persistent data is subject to the classic elements of information system design: read, write, update, and delete.

Information is thought about in Beynon-Davies’ work as mostly being about signaling (intentionally or otherwise), that is, as the communication of meaning that is sent by a sender and received and interpreted by a receiver. He draws on the work of biologists and ethologists, with particular attention to research on prairie dog signaling, to demonstrate how even nonlinguistic messages may be produced and interpreted.

Performa consists in the activity of performing a plan or organizational system. According to his Figure 1,^[95] moving from the data level through the information level to the performance level consists of the following: The form of data is structured into meaning, from which intentions arise, leading to actions. Thus, we start with the data, give it meaning and use it to inform, and then perform actions, collaboratively or singly, to achieve goals. As he states elsewhere, “Forma can be seen to encapsulate the objective nature of information, informa its subjective nature and performa its inter-subjective nature.”^[96]

SECOND INTERLUDE: DIKW

DIKW stands for data–information–knowledge–wisdom. Just as Popper’s three worlds frequently show up in considering information, so also does this sequence. Discussion of this sequence is based on the assumption that the terms go from the least to most processed or integrated, with data the rawest and wisdom the most rarefied.

Arguably, this view of these terms comes ultimately from their popular usage. Intuitively, we see each term in the sequence as more developed, “cooked,”^[97] or worked through than the term to its left. Discussions of this sequence, in more or less formally worked through thinking, show up in many works, including, at least, those of Houston and Harmon,^[98] Hammarberg,^[97] Meadow and Yuan,^[6] and Ferris.^[99] Sharma traced the hierarchy through the knowledge management and information science literature in the 1980s back to the poet T.S. Eliot in 1934.^[100] Thompson suggests that “signal” should be a fifth term in the sequence, preceding data (“Telecommunications” in *ELIS*).

Though this sequence may feel intuitively right, it is difficult to take it from its popular meaning and develop it into something sufficiently refined to be useful for research. Most discussions of DIKW really, at base,

elaborate the intuitive understanding and do not take theory much further. Frické concurs and argues that “the DIKW pyramid should be abandoned.”^[101]

DECONSTRUCTING “INFORMATION”

“Information” has had so much importance in the thinking of many disciplines, including library and information science, over the last 60 or more years that it is not surprising that the time has come where authors set out to debunk or “deflate” the importance of the concept of information. They choose various ways of doing this; three are illustrated in the succeeding text.

Ronald Day

In Ronald Day’s deconstruction of *The Modern Invention of Information*, he states that “I attempt to show how professional and authoritative texts about the social importance of information tried to use language (particularly through books) to construct a social, utopian value for information and helped to raise information and its connotations of factuality and quantitative measure to a privileged, even totalitarian, form of knowledge and discourse.”^[102] He says his objective is not to say what information “really is” nor to conclude that information is good or bad, but “rather that certain connotations of information, and the social and cultural privileging of certain technologies and techniques associated with it, are cultural and social productions that elevate certain values over other values. . . .”^[103] Thus, he is not defining so much as critiquing the uses of the term “information.”

Bernd Frohmann

Bernd Frohmann’s objective in his book *Deflating Information* is to replace the centrality of “information” as the focus of much of information studies and science studies with the centrality of practices surrounding documents.^[104] His objective is thus not so much defining or theorizing information, but rather, as his title says, “deflating information.”

“One of the aims of this book is to show how rich and varied the practices with scientific documents can be, especially compared to the simplistic idea that there is no more to the informativeness of a document than what happens in the mind of someone who understands it.”^[105]

Some would complain, however, that good research on information seeking has, from the beginning, also examined scientific practices around documents, and linked those practices to the subjective points of view of the people being studied. Most of the articles on information seeking in the “ancient” 1958 International Conference on Scientific Information^[106] or the 1960s era American Psychological Association’s Project on Scientific Information

in Psychology^[107] could be shown to have done that. What we can say of recent decades, though, is that consciousness of all the practices, situations, and cultural beliefs surrounding information seeking and use has grown substantially, and Frohmann's book-length treatment demonstrates that.

Jonathan Furner

Furner suggests that rather than relating information to epistemology, we should relate it to the philosophy of language. Further, "we shall find that philosophers of language have modeled the phenomena fundamental to human communication in ways that do not require us to commit to a separate concept of 'information.'" And "[o]nce the concepts of interest have been labeled with conventional names such as 'data,' 'meaning,' 'communication,' 'relevance,' etc., nothing is left (so it may be argued) to which to apply the term 'information.'" In fact, he claims that the entire field may be misnamed and "that its subject matter should more appropriately be treated as a branch of communication studies, semiotics, or library studies."^[108] Furner might not call himself a postmodernist, but the effort to design an approach that does without *the* central concept in a discipline has an objective very much in a postmodernist spirit of deconstructing hitherto core values and ideas.

He identifies what he considers to be the several ways in which "information" is used and discussed in information studies and categorizes them in three broad groupings as follows: "information-as-particular," namely, "utterances," "thoughts," and "situations"; "information-as-action," namely, "communication"; and "information-as-universal," namely, "informativeness" and "relevance."^[109] He then argues that other fields address most of these topics with deeper understanding and research results than information studies does and that even in those topic areas where information studies has done much work, such as relevance, we can draw from work in pragmatics and the philosophy of language.^[110]

One can certainly agree that we have not advanced as far as desirable in understanding information, and, as well, that we often lack an adequate theoretical basis out of which to develop our ideas. However, one can see this situation as a problem of failing to date to develop our unique intellectual substrate, rather than that we are reinventing lumpy versions of other disciplines' well-wrought wheels.

The universe of study of the physicist is the physical processes and dynamics that govern our universe; the universe of study of the biologist is the world of living things. The primary domain of study in the information disciplines is the world of exosomatic information and human beings' relationship to that world as creators, designers, and users. Heretofore, society has seen that world, if it noticed it at all, as merely an epiphenomenon of the real

world of things that matter. Increasingly, as the twenty-first century develops, we are more and more often grasping the reality that the world of information has become its own universe of study, one of immense importance to human beings, full of intriguing phenomena to observe and understand. That study should surely include identification of key terms, along with the provision of our own disciplinary definitions.

CONCLUSIONS

The understanding of the core concept of "information" in information science remains a highly contested area. Information is seen as

- A proposition, a structure, a message, or an event
- Requiring truth or indifferent to truth
- Socially embedded and under perpetual reinterpretation or as measurable in bits
- A worn-out idea deserving of dispatch or as an exciting conception understandable in terms of evolutionary forces

The much-debated concept of information remains at the lively heart of information science.

Information Arts

Christiane Paul

Jack Toolin

Whitney Museum of American Art, New York, U.S.A.

Abstract

This entry provides a survey of the field of information arts, an artistic practice that creatively and critically reflects on the collection, filtering, and dissemination of information. The term information arts is relatively new and used mostly as it relates to the information society of the digital age. This entry outlines the roots of contemporary information art practice in processes of information distribution and mass media and places it within the wider art historical context of works that have explored information flow and mass-mediated images. Among the topics addressed are the ways in which recent information artworks process data from sources such as science, humanities, and network technologies and the methods these artworks employ for giving information form, for example, data visualization and the construction of databases. This entry also briefly discusses the challenges that information art using new technologies poses to the traditional art world, ranging from presentation to collection and preservation.

INTRODUCTION

This entry explores the field of information arts and its relationship to information societies, its practitioners, their conceptual motivations, and the various manifestations their artworks take, from projected visualizations to performative interactions. A brief discussion about the historical development of the information society is included in order to elucidate information arts' relevance to that history, as well as its break from past cultural practice.

A data flow diagram depicts the range of data origins, the strategies employed by artists to process the data sets, as well as the various methods of presentation. Using examples, this entry presents two main artistic approaches to working with information, one more focused on formal and aesthetic concerns, the other addressing cultural and political aspects. Finally, this entry considers information arts in the context of the art institution, summarizing approaches to exhibition, and preservation.

DEFINING INFORMATION ARTS

It would be problematic to claim that information arts are a clearly defined field or a term that describes a specific kind of artistic practice in a specific medium. While one could argue that art throughout the centuries has been concerned with or addressed information in some form or another, the term "information arts" has been used only fairly recently. The term was formalized by Stephen Wilson when he published his book of the same name in 2002. Wilson describes the field as one primarily concerned with data as it relates to science and technology, making a strong case for the ubiquitous impact of these areas in the information

society.^[1] However, this seems too narrow an approach as it excludes valuable contributions by artists who, while working with information and its mechanisms for evaluation and distribution, do not directly comment on or use data derived from science or technology.

If one understands information science as an interdisciplinary field concerned with the collection, storage, classification, retrieval, and dissemination of information, one could say that information arts make the concerns of information science both their content and medium. Information arts consciously explore or critically address the issues surrounding the processing and distribution of information by making information itself the medium and carrier of this exploration.

The term information arts now seems inextricably interconnected with the information society that has been brought about by digital technologies and is occasionally understood as strictly digital or data driven. However, information arts are a wide-ranging category that can also be applied to analog techniques and technologies and has a history within artistic practice, as we will show in the following. We are addressing the topic with a rather broad scope, thinking of information as a cultural as well as numerical entity. While information arts are not identical with digital art or so-called new media art (art that uses digital technologies as a medium for production, storage, and distribution), these fields of artistic practice certainly overlap. One could argue that digital art is a subcategory of the broader field of information arts in that it explores and processes information by means of digital technologies only (e.g., as a data visualization or website) and predominantly understands data as digital binaries. The larger umbrella of information arts, by contrast, potentially engages with its subject

across a range of media—from print and analog radio and TV to digital media. Not all of digital art can automatically be understood as information art; a digital artwork that explores hyperlinked storytelling and narrative does not necessarily self-consciously address information processing and distribution. In terms of defining the field, one could therefore suggest that a portion of digital art—in which information is both medium and subject matter—is a subcategory of information arts at large.

A strong link between digital art and information arts in general is established by the use of algorithms or code—a procedure of formal instructions that accomplish a “result” in a finite number of steps—which forms the basis of digital or new media art. Information arts uses a variety of methods, both analog and digital, to process data but a significant portion of the practice relies on digital technologies and algorithms in this processing. The layer of code and instructions constitutes a conceptual level that connects to the artistic explorations of previous decades. Information arts can be understood as a larger category than digital art, as a field of artistic practice that consciously makes information—be it in digital form, contained in genetic code, or circulated by the mass media—its subject matter.

INFORMATION ARTS IN AN INFORMATION SOCIETY

Today, it is nothing new to think of our society as an “information society,” so much so that we might take for granted when and how this development occurred. Information, or the communication of information, was an important element in the development of ancient societies and has remained important ever since. The evolution of languages and the means for circulating those languages was a key for extending cultural influences, and the power of the societies generating them, from Babylon to Qatar. But one would not describe the late Roman Empire as an information society, despite the centralized authority over a large expanse and people of disparate backgrounds.

In fact, we typically do not think of information societies occurring until the twentieth century, and more precisely not until the latter half of the century as the economy moved from material goods to information goods. While it is not our intention to examine the evolution of information from its inception, a brief consideration of its growing role and importance to our civilization will allow us to better understand the development and relevance of what one might call the information arts.

When did the collection, classification, storage, and dissemination of information become important to society? Again, one could go back to early civilization, but a crucial moment would be after the Renaissance and the rise of rational humanism, during the Industrial Revolution, when

mechanization and automation provided for greater redundancy, predictability, and measurability—Taylorism was a symptom of this trend in business practice and philosophy, and Fordism was its crowning achievement. In the late nineteenth century, Frederick Winslow Taylor proposed that working environments and procedures be based upon analyses of the work to be done, with increased productivity being the goal, as opposed to methods adopted by convention. Fordism, a term coined by the Italian political theorist Antonio Gramsci, refers to the deskilled, task-oriented work common in twentieth-century manufacturing since Henry Ford implemented the assembly line. The economy became increasingly reliant upon efficiency and productivity, and in the meantime developing transportation and communication technologies allowed for a more dispersed clientele and a public whose solidarity increasingly defied geography and genetics.

Immigration was spurred by new technologies both because travel became easier and because booming industries lured people to travel great lengths for financial gain. The influx of immigrants in America precipitated a shift toward a greater use of images in journalism as it went “yellow” and coincided with the rise of the moving image, which was, in this regard, fortunate to be silent.

These changes did not go unnoticed by artists of the time: One can see examples of the influence of mechanization and technological idealism in cubism and futurism, while the Dadaists adopted rule-based methodologies for some of their art making, emphasizing procedure over product. It is not a surprise that today, in societies consumed by computation, the Dadaism is seen as one of the most influential art movements of the twentieth century. The conceptual artists of the late twentieth century are seen as descendents of these earlier explorations, and their de-emphasis of aesthetics and material as the central signifiers of art opened up the door for a growing number of practitioners from disciplines such as computer science, engineering, biology, and philosophy.

It was in the early twentieth century that Madison Avenue and Hollywood (not to mention the military) realized the power to persuade that the mass media possessed. However, despite the growing importance of mass-circulated information in this nascent stage, the economic engine of the West was still largely the production and distribution of hard goods, with the postwar boom yet to happen—information was mostly at the service of engineering and manufacturing. Radio, movies, and magazines made inroads into leisure time, but they all took a hit as television became the mass medium by the late 1950s. Consumerism reached new proportions as the mass media were there to guide and facilitate achieving a proper standard of living for the growing middle class. Art reflected these developments, with overt manifestations in the pop art movements of England and the United States, Richard Hamilton and Andy Warhol being prime examples,

respectively. While Hamilton and his colleagues in the Independent Group critiqued the growing trends of consumerism and the corporatization of contemporary society with wry satire, Warhol employed the visual language and marketing strategies of corporate culture to manufacture and disseminate the Warhol brand.

An appropriate parallel to these artists' approaches is the recent work of artist collectives @TMark and etoy. The former group undermines corporate authority through various strategies, among them the mirroring of websites, a common tactic of activist art projects. Artists register domain names similar to those of corporate entities or institutions, mirror the look of these entities' websites, but subvert their contents as an act of critique. In collaboration with The Yes Men, @TMark was involved in a December 2002 press release originating from the fake site Dow-Chemical.com that explained why Dow could not take responsibility for the Bhopal catastrophe, which resulted in an estimated 20,000 deaths over the years. The release created public outrage, as well as expansive press coverage and controversy.^[2] etoy frequently carry out acts designed to heighten their public profile, and hence increase their value as a cultural entity. In other words, they engage in branding. The work of these artists reveals identity as a cultural construct that is dependent upon the maintenance of a profile in the public, which is widely accepted as an entity established through communication. The value, or impact, of a given identity is reliant upon its circulation via various media, from print to the Internet. As etoy themselves state

The firm represents the core and code of the corporate sculpture, and controls, protects, promotes, and exploits the cultural substance (intellectual property) and the etoy. ART-COLLECTION. etoy intends to reinvest all financial earnings in art—the final link in the value chain.^[3] (Fig. 1)

Meanwhile, as corporations extended their reach, their desire for greater productivity was met by the burgeoning

computer industry. The UNiVersal Automatic Computer, which was capable of computing textual and numerical data, was the first commercially available computer, announced in 1951. While it took some years for computing to be adopted by industry at large and decades longer for it to become a fixture in the home, the concepts and methods that are the foundation of computing had manifestations in rule-based art from the late 1950s through the 1970s and beyond, such as Sol LeWitt's drawings, paintings, and structures, Fluxus' instructions for "being" art (one cannot overlook the relevance of Dada performance/poetry here), the psychogeographic explorations of the Situationists, the chance operations of John Cage's sound work, and the reiterative music of Steve Reich. Recognizing that technology had extended from the production floor of the factory to the cutting room of culture, artists like Nam June Paik, Vito Acconci, and Bruce Nauman began experimenting with video, and in the mid-1960s Experiments in Art and Technology, founded by engineers Billy Klüver and Fred Waldhauer and artists Robert Rauschenberg and Bob Whitman, melded the skills of engineer and artist to explore the possibilities of technologically enabled art.

Experiments in Art and Technology was far from the first such commingling of art and technology, after all photography and film have their roots in such experimentation; the linear perspective of Early Renaissance painting was based in mathematics, and architecture going back to antiquity followed mathematical principles for design and proportion. So is the emergence of the information arts of the late twentieth century anything new? Yes. While one can argue that information has been key to the existence and propagation of civilizations from their start, it is since the mid-twentieth century that the collection, classification, and dissemination of information has been such a force within society that economics, politics, and social relations depend upon it. In the United States, a

Fig. 1 etoy.CORPORATION History/Share Certificates. Screenshot.

process of deindustrialization began in the mid-1960s when the percentage of manufacturing employment peaked at 28%, dwindling by more than 10% over the next 10 years.^[4] This coincided with growth in the information industries and the growing economic activity related to the processing and distribution of information.

FROM DATA TO INFORMATION FLOW: THE PRACTICE AND PRODUCTION CYCLE OF INFORMATION ARTS

Essential to the concept of information arts is the “production cycle” of information itself, which—in its connection to all the previously mentioned aspects of information collection and dissemination—becomes the subject and means of artistic exploration. The Merriam-Webster Online Dictionary defines information as “the communication or reception of knowledge or intelligence” or “knowledge obtained from investigation, study, or instruction.”^[5] Derived from the Latin verb “informare,” which means “to put into form,” information is closely connected to the act of informing as imparting learning or instruction. Webster’s, as many other dictionaries and common language usage, to some extent conflates information with data, defining data as “factual information (as measurements or statistics) used as a basis for reasoning, discussion, or calculation.”^[6] A more precise definition and delineation of the two terms might be the understanding of information as processed data. In this sense, information would consist of the conclusions derived from the analysis of figures, statistics, etc. (data), which form the basis of reasoning. This meaning of information would be closer to Webster’s description of information as representation of data: “a signal or character (as in a

communication system or computer) representing data.” On a sidenote, the equation of information and knowledge seems equally problematic. David Sholle suggests to distinguish the two in terms of multiplicity, as well as temporal and spatial categories, arguing that (1) information is piecemeal and fragmented, while knowledge is structured and coherent; (2) information is timely and transitory, while knowledge is enduring and temporally expansive; and (3) information flows across spaces, while knowledge is a stock and located, yet spatially expansive.^[7]

Distinguishing characteristics aside, there is no doubt that information and data are closely related and feed into each other. Data commonly function as input into systems or programs that output information. However, information or segments thereof can either become or produce input data. David Sholle has pointed out that in information economics, information functions both as the resource providing input into the production process of commodities and the control of the market itself and as the output that is materialized and sold as a commodity.^[8]

The diagram in Fig. 2, which is meant to be a schematic outline rather than a definitive model, sketches some central aspects of the practice of information arts. The source data for an art project can be derived from areas as varied as the sciences (such as biotechnology and genetics or geographic information systems), the humanities (languages and literature, visual arts, and music), network processes (data flowing through or pertaining to digital networks), haptic or acoustic processes, etc.

Information arts process these data through the use of rules, algorithms and codes (instructions that accomplish a “result” in a finite number of steps), or other forms of encoding and transformation. It is important to note that code cannot be understood as separable from its overall structure. As Adrian Ward, Alex McLean, and Geoff Cox

Fig. 2 Paul/Toolin, flow diagram of the practice of information arts.

Fig. 3 Eduardo Kac, *Genesis* (1999). Transgenic work with artist-created bacteria, ultraviolet light, internet, video (detail), edition of 2, dimensions variable.

pointed out in “The Aesthetics of Generative Code,”^[9] the written form of code—as “a notation of an internal structure that the computer is executing, expressing ideas, logic, and decisions”—is “a computer-readable notation of logic” and not what the computer really executes. The execution takes place through various layers of interpreting and compiling. This layered interpretation and processing (by various means and methods) is a basic characteristic of information arts.

Eduardo Kac’s *Genesis* (Fig. 3) perfectly illustrates this process of multilayered interpretation. Taking textual and scientific data (from the field of genetics) as its source, *Genesis* uses encoding and the transformation of different materialities as a means of processing. For the project, Eduardo Kac created a synthetic “artist’s gene” by translating a sentence from the biblical book of Genesis (“Let man have dominion over the fish of the sea, and over the fowl of the air, and over every living thing that moves upon the earth”) into Morse code and converting the Morse code into DNA base pairs.^[10] The synthetic gene is cloned into plasmids, which are transformed into bacteria. In the gallery installation of the work, visitors encounter a pedestal with a petri dish containing the bacteria and, suspended over it, a UV that disrupts the DNA sequence in the plasmid and accelerates the mutation rate. Visitors to the *Genesis* website are able to remotely turn the UV light on, thus interfering with and influencing the process. Kac’s goal is to examine the relationship between information technology and science, as well as belief systems and ethics. The interplay between these fields is achieved by translating and transforming different forms of information, the result being the creation of a life form based on language and “code.” *Genesis* connects to the definition of information as the attribute inherent in and communicated by “alternative sequences or arrangements of something (as nucleotides in DNA or binary digits in a computer program) that produce specific effects.”^[5]

While Kac’s work manifests itself as a networked installation, information art can use numerous methods

to give information form, ranging from installation to a virtual reality environment or distribution over mobile devices, such as cell phones or personal digital assistants. The latter play an important role in locative media projects, which use a location in public space as a “canvas” for an art project and have become one of the most active and fast-growing areas in information arts. Locative media employ technologies such as the global positioning system for data gathering or allow their users to contribute to projects and share information via mobile devices. A number of art projects have focused on mapping and enhancing existing physical spaces and architectures, creating a virtual, public repository for information that supplements sites. Others have focused on transforming mobile devices from mere communication tools into personal measurement instruments and enabling people to collect and share data about their surroundings and environment. Other common methods for making information manifest are the construction of databases and data visualization.

As mentioned before, information art that involves the digital medium always consists of a “back end” of algorithms and data sets that often remain hidden behind a visible “front end” that is experienced by the viewer/user. This front end is produced by the code and algorithms that interpret the back end data, and the results can range from complex visuals to more abstract communication processes. Some information artworks are predominantly visual; other works are more focused on raw data and the database model. Given the fact that database structure in the broadest sense lies at the root of digital media, it is only natural that so-called database aesthetics play a major role in information arts.

The 1990s were a decade of major digitization, where libraries, archives, and museum collections were translated into digital format. While a database is now commonly understood as a computerized record keeping system, it is essentially a structured collection of data that stands in the tradition of “data containers” such as a book,

a library, an archive, or Wunderkammer. Every “container” of information ultimately constitutes a dataspace and information architecture of its own, even though its characteristics are quite different from the virtual, dynamic dataspace. What distinguishes digital databases from their analog predecessors is their inherent possibility for the retrieval and filtering of data in multiple ways, allowing for new forms of relational connections.

Databases can be distinguished according to different “data models”—that is, data containers and the ways in which data are stored in and retrieved from them. A database essentially is a system that comprises three levels: (1) the hardware that stores the data; (2) the software that allows for housing the data in its respective container and for retrieving, filtering, and processing them; (3) and the users who add a further level in understanding the data as information.

In the field of information arts and digital art, the term “database aesthetics” is frequently used to describe the aesthetic principles that are applied in imposing the logic of the database to any type of information or filtering data collections or visualizing data. In that sense, database aesthetics often becomes a conceptual, potential, and cultural form—a way of constructing information by revealing (visual) patterns of knowledge, beliefs, and social behavior. Generally speaking, the aesthetics of a database are inherently relational, be it on the level of potential (the data stored in the data container) or the actual relationships established by the software component. Database aesthetics suggest the possibilities of tracing process—individual, cultural, communicative—in its various forms on the basis of data. Largely brought about by digital technologies, database aesthetics itself has become

an important cultural narrative in information arts, constituting a shift toward a relational, networked approach to gathering and creating information and knowledge about cultural specifics.

Examples of information arts that apply a database model to reveal information about cultural and individual values are George Legrady’s projects *Pockets Full of Memories* (2001) and *Slippery Traces* (1997). *Pockets Full of Memories*, an installation with an accompanying website,^[11] explicitly focuses on the “mechanics” of database construction and the way in which we derive informational value from databases (Fig. 4). It creates an “anatomy” of personal value by inviting visitors to digitally scan an object in their possession at a scanning station and answer a set of questions regarding the object, rating it according to certain attributes (old/new, soft/hard, natural/synthetic, functional/symbolic, personal/nonpersonal, useful/useless, etc.). The algorithm used to process the data is the Kohonen self-organizing algorithm, which classifies the scanned objects in a two-dimensional map based on similarities in their descriptions and attribute ratings. The Kohonen map generates a grid with random values for each point in the grid and all the data categories for each object; the algorithm classifies one object after the other and positions it where it finds the closest values for the respective object, so that over time all the objects are positioned in proximity to the ones with similar values. Users can review each object’s data and add their own personal comments and stories. The mapping of these objects illuminates how each object is contextualized by its surrounding data and underscores the absurdities of classifying objects endowed with personal meaning.

Fig. 4 George Legrady, *Pockets Full of Memories* (2001). Screenshot of the interface.

The information conveyed is obviously very much dependent on the database system as a whole—the interplay between the container, the algorithms, and the interpretation of the user. Database categories and the algorithms filtering them are never value-free but always inscribed with an interpretative angle.

Closely related to the construction of databases, data visualization is another method of making processed data manifest as information. Data visualization can be defined as the creation of dynamic visual models for data sets. For any given set of data, there are multiple possibilities for giving it a visual form, which in turn lend themselves to reconfiguration. The dynamics of the visualization and interface are yet another layer of processing that provides a context for deriving information. Context becomes key when it comes to the success of the visualization process. While there needs to be a certain focus on data changes at any given point, the visualization tends to turn into a form of wallpaper (no matter how beautiful it is) if it loses the larger context of its underlying data set.

The issue of potential relationships between the data structure or data stream and its visualization is perfectly captured by the Radical Software Group's project *Carnivore* (2001–present).^[12] The project is inspired by the software DCS1000 (nicknamed “Carnivore”), which is used by the FBI to perform electronic wiretaps and search for certain “suspicious” keywords via packet sniffing—a software-based process of intercepting, logging, and analyzing the data packets sent over a digital network. Using network traffic on a specific local area network as its data source, the project processes the data through software that performs packet sniffing. The resulting data stream is visualized by the numerous “client” applications that

artists have created since the project's inception. At the core of the Carnivore project are the unlimited possibilities of visualizing the server's data stream in a collaborative, open-source way. Jonah Brucker-Cohen's *Police State* (2003) addresses and subverts the process of surveillance itself (Fig. 5). In *Police State*, the processing of the data stream takes the form of both a visualization and a physical installation. The client sniffs the network looking for keywords relating to domestic U.S. terrorism and assigns the identified text to an active police radio code, which is translated to its binary equivalent and sent to 20 radio-controlled toy police cars as a movement sequence. Controlled by the very data that law enforcement is searching for, the police cars perform a synchronized “dance,” driven by their own surveillance.

The previous examples illustrate ways in which data are processed (through algorithms, encoding, and transformation) and methods of engaging with the data to give it form (through installations, construction of databases, or data visualization). As any information, these and other information art projects enter the larger cultural and social sphere through the media—be it the mass media of print publications and television. The technologies and distribution process of the media, as well as the information circulated by them, again produce data that information arts make their subject. An excellent example of this recapitulation of media imagery is a 2006 project by Eva and Franco Mattes (aka 100101110101101) titled *13 Most Beautiful Avatars*. This project consists of “pictures of self-portraits” featuring the avatars made by inhabitants of the virtual world Second Life, which reveal a desire to appear as someone other, someone closer to the ideals of beauty commonly seen in Western mass media. The

Fig. 5 Jonah Brucker-Cohen, *Police State* (2003) at the exhibition “Source Code,” Eyebeam, New York City (May 31–August 11, 2007).

project directly references two of Andy Warhol's works of the 1960, *Thirteen Most Beautiful Boys* and *Thirteen Most Beautiful Women*. The Mattes' piece is one of the many utilizing the imagery and implications of popular culture in virtual worlds and computer games.

APPROACHES TO INFORMATION ARTS: FORMALISM VERSUS CULTURALISM

The practice and data flow of information arts we have outlined so far makes obvious that the field is not at all unified but spans various artistic media and methods. This raises the question whether it is possible to identify major conceptual categories for understanding information arts rather than relying on the rather formal distinctions between different methods for processing and materializing data. Categories that may be helpful for a conceptual approach are those of formalism versus culturalism, which have been used in software art, a subcategory of digital art that focuses on artist-written code. One can argue that there is a fairly strong connection between software art, which relies on processing through code and algorithms, and information arts, which involve either the same methods or rules and "encoding" in the broadest sense for transforming data.

The jury of the pioneering software art festival Read_Me 1.2 (2002)^[13] broadly defined software art as works based on code as formal instructions or offering a cultural reflection of software. The former would apply to forms such as generative art and code poetry that put an emphasis on the aesthetics of formal instructions; the latter would apply to categories such as manipulations of existing software (cracks and patches or plug-ins) or political and activist software (e.g., cease-and-desist-ware and software resistance), which offers a critical reflection of software's cultural status, its encoded political or commercial agenda. Games, artistic tools, and conceptual software could fall into either of these two groups, depending on the execution of the respective project and the weight it places on formal aspects or critical reflection. One can rephrase this classification of software art—as focused either on code as formal instructions or on cultural reflection—as a manifestation of formalism versus culturalism. In his essay "Concepts, Notations, Software, Art," Florian Cramer also suggests this distinction with regard to software art: "a cultural, politically coded construct" versus a focus on "the formal poetics and aesthetics of software code and individual subjectivity expressed in algorithms."^[14] Applying the formalism versus culturalism distinction to the information art projects discussed earlier, one could propose that Kac's *Genesis* offers cultural reflections on biotechnology and belief systems. As opposed to Brucker-Cohen's *Police State*, which explores surveillance and political aspects, Napier's *Black and White* software is a mostly formally and aesthetically

oriented project (as many other data visualizations). Legrady's projects would also be culturally focused, be it in the interpretation of imagery or the personal value of objects. The projects of etoy, mentioned in the beginning, can be seen as a cultural investigation of the "products" of information society.

It is important to note that, as conceptual art, information arts cannot be evaluated in terms of classical standards of "visual beauty" since they may take the form of a database that concentrates on its own structure and underlying "politics" rather than the visual aspects of its contents. As Cramer puts it, the focus on the purely perceptual aesthetics of art "is a straight continuation of romanticist philosophy and its privileging of aisthesis (perception) over poesis (construction), cheapened into a restrained concept of art as only that what is tactile, audible, and visible."^[15] The range of information art projects combines both aspects and raises issues about the status of representation in an information society, which has been much discussed. If one defines representation as a "likeness" or image of an external referent (an "object" or "scene" in the broadest sense), information arts in general ultimately represent data. One could draw the conclusion that we are facing a major transformation of the status of representation itself, which becomes a process that involves data processing and is concerned at least as much with algorithmic rules and conceptual aspects as visual, textual, and acoustic manifestations.

INFORMATION ARTS IN THE MUSEUM

Over the decades, there have been a number of digital and media art exhibitions that featured information arts and some galleries have consistently presented it, but shows in an institutional context have mostly taken place at media centers and museums such as InterCommunication Center in Tokyo or Zentrum für Kultur und Medien (Center for Culture and Media) in Karlsruhe, Germany, and the art mostly found its exhibition venues under the umbrella of conferences, festivals, and symposia devoted to art and technology, among them the Ars Electronica Festival (Linz, Austria), the art show of the U.S.-based Special Interest Group for Computer Graphics and Interactive Techniques conference and ISEA International (founded in the Netherlands) and festivals such as European Media Art Festival (Osnabrück, Germany), Dutch Electronic Art Festival, Next Five Minutes (Netherlands), and Transmediale (Berlin, Germany). Traditional art institutions so far have not played a major role in the production and development of information art projects, which have been supported mostly by the research labs of educational institutions or media centers, such as V2 in the Netherlands or the Banff New Media Institute in Canada.

Information arts that do not take the form of more traditional media still pose quite a few challenges to the

traditional art world, ranging from presentation to collection and preservation. Digital print, photography, and sculpture represent the object-oriented work that museums are equipped for, but time-based, interactive works of information art raise numerous issues. These issues to a large extent are not medium specific but apply to any time-based and interactive work, be it a video, a performance, or a robotic sculpture. Information art often requires audience engagement and does not reveal its content at a glance. The basic rule of museums, “Please do not touch the art,” suddenly does not apply anymore and large segments of the audience are still hesitant to physically engage with artwork. Works of information art can be expensive to show and ideally require consistent maintenance. Museum buildings are mostly based on the “white cube” model rather than completely wired and equipped with flexible presentation systems. Information arts make us reconsider our traditional notions of space and architecture and often require the translation of information architecture or characteristics of virtual spaces into physical space. Information arts relying on new technologies ideally require a parallel, distributed, living information space that is open to artistic interference—a space for exchange, collaborative creation, and presentation that is transparent and flexible.

The specific challenges that a digital work of information art poses are dependent on the form it takes, be it a (networked) interactive installation, an online data visualization, a work involving mobile devices, or an immersive virtual reality piece. While some information art projects can be installed according to specified parameters (such as height, width, and defined lighting requirements), the variability and modularity inherent to the digital medium often means that a work can be shown in very different ways and has to be reconfigured for a specific space. Variability entails a fluent transition between the different manifestations that information art can take: The same work might be shown, for example, as an installation, projection, or kiosk setup.

Information art that has been created for the Internet tends to be particularly challenging to show within a gallery. Internet art has been created to be seen by anyone, anywhere, and anytime (provided one has access to the Internet) and doesn’t need a museum to be presented or introduced to the public. In the online world, the branding of the physical gallery and museum does not necessarily function as a signifier of status. However, physical art spaces such as galleries, museums, and festivals also play an important role when it comes to net-based art in that they provide context for the work, chronicle its developments, assist in its preservation, and expand its audience. Models for presenting Internet art in an institutional context have been widely discussed.^[16] Internet art often requires a relatively private engagement over a longer period of time, and in order to create an environment for this experience, institutions have often presented the art in

a separate area of a public space, which raised the criticism of “ghettoization.” The setup in a separate “lounge area” has the advantage of inviting people to spend more time with a piece but prevents that the art can be seen in the context of more traditional media and enter into a dialogue with them.

Ultimately, the physical environment should be defined by what a work of information art requires, and it is important to establish a connection between the physical space and the respective information architecture.

The collection of digitally based information art projects is yet another topic that has been hotly debated. The value of art is—at least when it comes to traditional models of the art world—inextricably connected to its economic value. However, the notion of the original and the scarcity-equals-value model do not necessarily work for information art, which could consist of a set of instructions or a dynamic process. Collecting is less problematic in the case of digital installations, which ultimately are objects, or software art (which sometimes comes with custom hardware), which can be sold as a limited edition as photography or video. Information art can also draw on precedents in the realm of conceptual art; instruction-based works such as Sol LeWitt’s wall drawings have been collected by major museums. In the case of Internet art, the hosting of the source code on the respective museum’s server constitutes a form of ownership. As opposed to traditional artworks, net projects are on view permanently and not only when the museum decides to mount them in a gallery.

The process of collecting art entails the responsibility of maintaining it, which is one of the biggest challenges posed by information art projects involving new technologies. The process-oriented nature of many of these works makes it evident that preserving the art requires new models and criteria for documentation and preservation. The main strategies for preservation are storage, emulation, and migration. Storage means the archiving of software and hardware as it continues to be developed, an obviously not very elegant solution that quickly requires large storage facilities. Emulation is the use of software for imitating the original version of a project by “re-creating” the software or operating systems that the project requires, and migration means an upgrade to the next version of hardware/software.^[17] Worldwide, numerous preservation initiatives are creating standards for preserving media works that involve new technologies. Among them are the Variable Media Network^[18]—a consortium project by the University of California Berkeley Art Museum and Pacific Film Archive, the University of Maine, the Solomon R. Guggenheim Museum, Franklin Furnace Archive, and Rhizome.org, among others—and International Network for the Conservation of Contemporary Art.^[19] These initiatives are developing vocabulary for catalog records, standards that allow institutions to exchange the metadata gathered for these records, and tools

(such as database systems) for the cataloging of process-oriented art. Among these tools is the “Variable Media Questionnaire,” which enables artists and museum and media consultants to identify artist-approved strategies for preserving artwork and to define the behaviors of artworks in a media-independent way. Describing artworks according to categories that are not specific to any particular medium but allow to establish a common ground beyond materiality seems to be particularly relevant for approaching the conservation of information arts, which are not bound to any specific medium.

CONCLUSION

Cultural developments in the late twentieth century have produced information societies that make it imperative for artists to be aware of or engage with changing modes of cultural production. The expansion of digital technologies and their impact on our lives and cultures will induce the creation of even more data sets, information, and research and consequentially more information artworks reflecting and critically engaging with this cultural impact. The ways in which artists encode and transform data will presumably evolve along with the latest research and technologies for data processing. The methods and platforms that artworks employ to give information in physical and visual form will also develop along with research and technologies. The pervasiveness of mobile technologies has already led to a proliferation of artwork using networked mobile devices.

The terminology for art forms involving new technologies has always been fluid and gone through numerous changes over the past few decades. Labels aside, the artistic practice that involves information circulating through research, science, technologies, and media distribution systems is certainly here to stay and will grow. Most likely information arts will always be an evolving field and exist in multiple contexts, supported and presented by art and technology centers, research and development labs, and hopefully traditional art institutions.

Information Behavior

Marcia J. Bates

*Department of Information Studies, Graduate School of Education and Information Studies,
University of California, Los Angeles (UCLA), Los Angeles, California, U.S.A.*

Abstract

“Information behavior” is the currently preferred term used to describe the many ways in which human beings interact with information, in particular, the ways in which people seek and utilize information. The broad history of research on information-seeking behavior over the last 50–60 years is reviewed, major landmarks are identified, and current directions in research are discussed.

INTRODUCTION

“Information behavior” is the currently preferred term used to describe the many ways in which human beings interact with information, in particular, the ways in which people seek and utilize information. Information behavior is also the term of art used in library and information science to refer to a subdiscipline that engages in a wide range of types of research conducted in order to understand the human relationship to information.

Interest in this area developed out of several streams. Librarians wanted to understand library users better, government agencies wanted to understand how scientists and engineers used technical information in order to promote more rapid uptake of new research results, and social scientists generally were interested in the social uses of information in a variety of senses. In more recent years, social studies of information technology and social informatics have contributed to this area as well. Within library and information science, these various streams of research are drawn on for what they can contribute to a richer understanding of information behavior.

INFORMATION

What, then, is information? Here, rather than review the many senses in which this term has been interpreted in the field (see ELIS entry “Information”), we will rely on a sense of the term that is an extended understanding of the concept as used in general conversation. We all recognize that people search for information on, say, the history of a small town, the population of Turkey, or how to do foreign exchange trading online. All these examples make a reasonable match with the generally understood sense of information as being factual, statistical, and/or procedural.

“Information,” however, is used in a broader sense as well in the world of information behavior research. The term is generally assumed to cover all instances where

people interact with their environment in any such way that leaves some impression on them—that is, adds or changes their knowledge store. These impressions can include the emotional changes that result from reading a novel or learning that one’s friend is ill. These changes can also reflect complex interactions where information combines with preexisting knowledge to make new understandings or enables the individual to deduce or induce new thoughts and ideas. As the Hans Christian Andersen tale suggested, the ugly duckling did not realize that he was a swan until he came in contact with swans, saw his reflection in water, and figured out that he was himself a swan, too.^[1]

These information interactions can also leave a negative impact—one may ignore, deny, or reject information.^[2] (See also an excellent early analysis of relations to information by Atkin.^[3]) One may also simply discover that nothing has changed—the university admissions letter still has not come in the mail. This negative news is, of course, informative in its own way, just as a person who has ignored information has often, in some way or other, nonetheless absorbed it. In fact, probably the largest amount of all information taken in by human beings is that received passively—simply through being aware—that is absorbed in the context of daily living.^[4]

Is this not a very broad understanding of information behavior? Indeed, does it not cover all interactions people have with their environment? Bates has argued:

In comparison to other social and behavioral science fields, we are always looking for the red thread of information in the social texture of people’s lives. When we study people we do so with the purpose of understanding information creation, seeking, and use. We do not just study people in general. . . . In communications research, a cousin to our field, the emphasis is on the communication process and its effects on people; in information science we study that process *in service of information transfer*.^[5]

Bates goes on to provide a specific example:

... [T]here are social scientists today who are observing people doing collaborative work through new types of networked systems in the field of computer-supported cooperative work (CSCW). The sociologist or social psychologist identifies and describes the network of relationships and the social hierarchy that develops under these circumstances. . . .

The information scientist, on the other hand, follows the information That's the red thread in the social tapestry. When we look at that social hierarchy, we are not interested in the hierarchy per se, but, rather, we ask how it impedes or promotes the transfer of information. We ask what kinds of information people prefer to communicate through this or that new channel of information technology. We always follow the information.^[5]

Thus, the study of information behavior can cast a very wide net, looking into both individual interactions and large-scale complex group and societal interactions with information. Indeed, as we shall see, the variety of contexts in which information behavior has been studied demonstrates this breadth. But information behavior research is not communication, psychology, education, sociology, or social impacts of technology research, though all those disciplines may find the work interesting to discover. Rather, information behavior research actually studies—and largely limits itself to—information-related behavior.

HISTORY OF INFORMATION BEHAVIOR RESEARCH

From the earliest days, librarianship in the United States had a commitment to care about and serve the users of libraries. In the founding year of American professional librarianship, 1876, Samuel Green wrote to encourage librarians to “mingle freely” with the library’s users “and help them in every way.”^[6] In the mid-twentieth century, the great Indian librarian, S.R. Ranganathan, promulgated his Five Laws of Librarianship, which were very much oriented to the library user:

1. Books are for use.
2. Every reader, his book.
3. Every book its reader.
4. Save the time of the reader.
5. The library is a growing organism.^[7]

However, for many decades that commitment remained largely on the plane of values and had little other than anecdotal data upon which to develop library services. In the 1930s, the Graduate Library School at the University of Chicago^[8] introduced the first doctoral degree in library science in the United States. Sophisticated social science

researchers, such as Douglas Waples and Bernard Berelson, brought their skills to the field. Waples^[9] did research on reader preferences, and Berelson, among other things, produced a compendium of results from dozens of studies on public library use.^[10,11]

The experiences associated with the operation of “Big Science” during World War II—major projects such as the development of the atom bomb—led government leaders to see the advantages in improving the distribution and transfer of information on new discoveries to other scientists and engineers. Major conferences on scientific information, in 1948 and 1959, led to a substantial amount of money being invested during the 1950s and 1960s in research on how scientists gathered and used information in their research work. Major example publications were the proceedings of the two science information conferences.^[12,13] The 21-report series “Project on Scientific Information Exchange in Psychology” from the American Psychological Association,^[14] and the work of Garvey et al. on several disciplines.^[15,16] Other influential early works include publications by Derek de Solla Price,^[17,18] Diana Crane,^[19] and A.J. Meadows.^[20] (Note: In order to keep this entry’s long bibliography from being even longer, referenced items are often only a sample of a person’s work, and when a series of articles comes out from a project, generally only the last article in the series is referenced.)

Early on, studies on information behavior were called “use studies,”^[21] studies of “information seeking and gathering,” or studies of “information needs and uses.”^[22] Gradually, the term “information-seeking research” was used to include all kinds of research on people’s interaction with information.

More recently, however, some researchers came to feel that “information seeking” suggested only explicit efforts to locate information and did not include the many other ways people and information interacted. In the 1990s, the term “information behavior” came into wide use to replace “information seeking.” The Old Guard objected that the phrase is a non sequitur—information does not “behave”—but, they lost out, and “information behavior” remains the most commonly used term today.

During the 1960s, in particular, generous funding was available in the United States for social science research, and a great deal of knowledge, based on large, well-designed studies, was developed regarding the social aspects of scientific communication and information use.^[23–25] Important studies were also produced on information use and library use by the general public.^[26–29] Focus in the larger society during the 1960s and 1970s on identity politics of race, gender, sexual orientation, and the economically underprivileged also led to research attention being directed to information seeking of the corresponding population groups.

In the late 1960s and early 1970s, this research began to be taught in library and information educational programs

in North America.^[30] As scientists had been studied according to their disciplines—physics, biology, etc.—and many members of the general public had been studied by their social identities—the poor, the elderly, etc.—there was a tendency to study information-related behavior by looking at groups of these sorts. For example, an invited conference on “information service needs of the nation” was funded by the U.S. National Commission on Libraries and Information Science in 1973. Presentations were structured in a parallel format to address the needs of a number of groups, including people working in science, agriculture, business, labor, biomedicine, the arts, social services, as well as children, the geographically remote, the economically and socially deprived, the institutionalized, and the mentally and physically handicapped, among others.^[31]

After the earlier attention to the natural sciences, during the 1970s research attention turned to information transfer in the social sciences. Grant funding in the United States receded, and pride of place went to Great Britain, where several researchers engaged in creative and revealing research on information seeking and use in the social sciences.^[32–34]

Finally, in the 1980s and 1990s the underfunded humanities at last got their due,^[35–38] particularly with the support of large institutions such as the J. Paul Getty Trust.^[39] In the 1990s, the needs of interdisciplinary and area studies researchers were addressed.^[40] See, especially, Carole Palmer, as Issue Editor, of an issue of *Library Trends* on interdisciplinary information seeking,^[41] as well as her subsequent book.^[42]

Over the decades, varying amounts of information behavior research has been done in various professional contexts as well, including the health sciences,^[43] law,^[44] and business.^[45] Among the professions, it is almost certainly the health sciences where the largest body of information behavior research has been done—probably due to abundant funding—while the education profession, despite the importance of information seeking for teachers, seems, mysteriously, to have drawn very little attention.^[46,47]

In the 2000s, Kari and Hartel made a persuasive case for studying the information behavior of people engaged in activities aimed at fulfillment and self-realization, and their own research provided examples of what could be learned along this line.^[48] Caidi, Allard, and Quirke review another recently growing area of research: immigrant information seeking and use.^[49]

The sweeping impact of use of the Internet and of mobile devices has increasingly dominated the working and living of all the groups reviewed earlier. Recent extensive studies include Antonijevic and Cahoy's on scholars' information practices,^[50] Mizrahi and Bates^[51] on the practices of undergraduate college students, and Beheshti and Large's book on current uses by children and teens.^[52]

Throughout the years, a number of models have been proposed to characterize various aspects of information behavior. Paisley beautifully characterized the subjective world of the scientist as constituting a series of contexts—local work environment, research specialty, discipline, larger cultural and political world, etc.^[24] In 1981, Tom Wilson described information seeking in general in a model^[53] that was subsequently very widely used and also reviewed a wide range of information behavior models in 1999.^[54] Belkin et al. propounded the concept of “anomalous state of knowledge,” or ASK,^[55] as characterizing many information needs. That is to say, they argued that the information need is often complex and requires an extensive description to cover all the factors really at play in people's requests. Kuhlthau's Information Search Process model, based on extensive research, demonstrated how intricately the conceptualization of a paper or project was bound up with confusions and problems in searching for information.^[56] Bates' “berrypicking,” that is, picking up a bit of knowledge here and a bit of knowledge there, was seen to be an appropriate description of much of human searching to meet information needs,^[57] in contrast to the previous generally assumed simple query that could be answered by a single retrieval from just one database.

Though extensive research on information seeking inside and outside of library and information science had been going on since the 1950s, it was an article by Dervin and Nilan in 1986,^[58] however, that seemed to provide the impetus for a great increase in interest in the subject in library and information science. The authors articulated the value of placing the user/searcher at the center of research, and paying close attention to the internal motivations and needs of the information seeker. From a minority interest of a relatively few people, information behavior research exploded in LIS after that article appeared, and doctoral students flocked to the subject area. For example, the number of articles dubbed “Use studies,” the standard term used in Wilson Web's article database *Library Literature and Information Full Text*, doubled per year in the 5 years between 1985 and 1990—from 76 to 155—while in the subsequent 18 years, the annual number has gone up by less than 60% to 245 in 2008 (author's database search). (Of course, these results could be artifacts of the publisher's indexing practices, and a fuller exploration would be needed to verify this conclusion.)

In particular, Dervin's conception of “sensemaking,” the effort of people to make sense of many aspects of their lives through information seeking and use, has been a dominating force in recent research on information behavior.^[59]

Dervin dismissed prior studies on grounds that “the studies assumed that the information brick was being thrown into the empty bucket”—that is, into the user of information.^[60] In one blow, this clever metaphor both characterized and caricatured much of the more classically empirical scientific approaches to research on information

behavior and gave qualitative research techniques and philosophies a boost. Dervin's "brick" image was unfair to the many researchers who did not take a simplistic view of information transfer, including many of the people mentioned in this article to this point.^[61] However, her emphasis on the importance of sense-making in motivating information seeking legitimated the subsequent emphasis on qualitative techniques in the field and enlarged the perspective of the whole subdiscipline of information behavior.

Indeed, over the years, increasing dissatisfaction was expressed by some researchers toward the prior orientation either to the individual seeking information or to studying the tendencies and preferences of large social groups, such as physicists or older people. These researchers sought to expand information behavior research, drawing on several theoretical paradigms of interest in the social sciences, such as social constructivism, social constructionism, and ethnographic techniques.^[62]

The surest sign of this broader interest came in the form of the "Information Seeking in Context (ISIC)" conference that came to be presented every other year, mostly in Europe, beginning in 1996.^[63] Conference attendees have sought to study information behavior in a way that goes beyond traditional research designs. They argue that context must be understood in a much fuller sense; they argue for rich, detailed, qualitative study of specific situations and contexts in order to understand the very nuanced ways in which people might receive and shape information.

They draw upon many different information-related theories and models,^[64] as well as on the many varieties of metatheoretical and philosophical perspectives that have become popular in the social sciences and humanities.^[65] See, as examples of these newer approaches, Ellis' grounded theory approach,^[66] Talja's discourse analysis of the culture of music in relation to libraries,^[67] Xu's application of activity theory to interactive information retrieval,^[68] Reddy and Jansen's ethnographic study of collaborative information behavior in healthcare,^[69] Limberg's^[70] and Ford's^[71,72] use of educational theory, and Srinivasan and Pyati's critical reexamination of information environments for diasporic groups.^[73]

At the same time, research drawing on other, more classically scientific and engineering methodologies did not disappear. See Fidel and Pejtersen's use of the Cognitive Work Analysis Framework,^[74,75] Sandstrom and Sandstrom's analysis of the methods of scientific anthropology as applied in library and information science,^[76] Nicholas et al.'s study of online information seeking through transaction log analysis,^[77] and even Bates' use of biological and evolutionary concepts in her recent work on information^[78] and browsing.^[79]

Perhaps the greatest sign of maturity of the field of information behavior research came with the publication—at last!—of the first book comprehensively addressing

information seeking, by Donald Case, in 2002, third edition in 2012.^[80]

The popularity of the ISIC conferences demonstrates the recent efflorescence of qualitative information behavior research beyond the borders of the (sometimes self-absorbed) research culture of the United States. Scholars from the United Kingdom (Tom Wilson, David Ellis, Nigel Ford, Elizabeth Davenport), Ireland (Crystal Fulton), Scandinavia (Louise Limberg, Olof Sundin, Annelise Mark Pejtersen), and Finland (Pertti Vakkari, Reijo Savolainen, Sanna Talja, Jannica Heinström) have presented and published at ISIC and elsewhere. Australian (Kirsty Williamson, Theresa Anderson) and Canadian researchers (Heidi Julien, Karen Fisher, Gloria Leckie, Lynne McKechnie, Pam McKenzie, Roma Harris, Chun Wei Choo) have also been very active in recent years.

Recently, Savolainen may have marked the beginning of a new phase in information research when he urged that the qualitative research on information behavior be called instead the study of "information practice."^[81] He argued that the concept of "information behavior" is primarily associated with the cognitive viewpoint, while "information practice is mainly inspired by the ideas of social constructivism."^[81]

The concepts of information behavior and information practice both seem to refer to the ways in which people "deal with information." The major difference is that within the discourse on information behavior, the 'dealing with information' is primarily seen to be triggered by needs and motives, while the discourse on information practice accentuates the continuity and habitualization of activities affected and shaped by social and cultural factors . . .^[82]

More recently, Huizing and Cavanagh have enlarged and systematized the theory and methodology of research on information practice.^[83] Their lucid exposition of this methodology is a good fit for the nature of information behavior study. They break down the traditional (and tired) contrast between the subjective and objective, they give physical objects the important role they should have in any theory of people and information, and they identify the dynamic nature of information seeking, without dissolving the study of it into confusing and nongeneralizable sets of very short-term and local acts. Huizing and Cavanagh's approach provides what is perhaps the best guiding philosophy at this time for further information behavior research.

In the last several years, there has also been a very active Special Interest Group on Information Behavior, founded by Barbara Wildemuth and Karen Fisher, among others, in the American Society for Information Science and Technology, which has held a number of preconferences and conference sessions, and offered awards for research in the area.

To follow the development of the research in this area, one can read the several chapters on the subject, starting with Menzel's in 1966^[22] and ending with Fisher and Julien's in 2009,^[84] which appeared periodically in the *Annual Review of Information Science and Technology*. (That review publication has now been subsumed within the *Journal of the Association for Information Science and Technology*.)

INFORMATION SEARCHING VERSUS INFORMATION SEEKING

This discussion addressed research on how people interact with information, how and when they seek information, and what uses they make of it. But it should be understood that throughout this period of time a parallel body of research and practical application was continuing that addressed the specifics of *the act of searching itself*. That is, in working with paper and online resources, many problems were encountered and skills needed to succeed in the specific acts associated with locating information in a paper or online resource. Bates' articles on information-searching tactics and search techniques^[85,86] promoted greater attention to the complexities of identifying sources and working one's way through resources to locate the desired information. A long line of research followed that addressed both search success and desirable design features in information systems to promote ease of use^[87-91] (See also ELIS entry "Information searching and search models."). Even browsing, normally seen as the most unstructured method of information searching, came in for considerable attention.^[79,92,93]

ROLE OF TECHNOLOGY IN INFORMATION BEHAVIOR RESEARCH

In order to simplify the narrative line, the aforementioned discussion made little mention of the role of technology in information seeking and research on information seeking. But, in fact, the extraordinary changes in information technology (IT) over the last 50–60 years have meant that a great deal of information behavior research has also been concerned with impacts of and reactions to the kinds of interactions people experience when using new technologies for finding and communicating information.

Focus on impacts of, and roles of, IT in information behavior has been intertwined to a greater and lesser extent with the information behavior research over these decades. Early studies took a fairly stable, largely paper-based environment for granted. Indeed, Garvey's research^[23] made salient, perhaps for the first time for many readers of his work, the huge, complex scientific publication cycle, from early tentative verbal presentation at talks all the way through conference presentations,

summary reports, journal publication, annual reviews, and, finally, incorporation of the scientific results into the established canon in textbooks.

But consciousness of the complexity of the production and publication of science was soon joined by efforts to improve, especially to speed up, the collection, storage, organization, and dissemination of that information.

Indeed, the entire discipline of information science has, in one sense, been the story of the successive absorption of a long series of IT innovations, followed, in each case, by research on the impacts of those innovations, and efforts to improve access to information through optimal design of those innovations. With the excitement generated by each new technology, the relatively stable underlying human behaviors and reactions were sometimes forgotten, and the new technology instead seen as the source of a totally new information-seeking landscape. One thing we now know, however, after a lot of research on those successive waves of new technology, is that underlying human propensities with regard to information emerge again and again as each new technology becomes familiar and its use second nature. Often, in the end, the new technologies offer speed and ease of use, while otherwise replicating previous social structures and interactions.

We know, for example, that people are willing to commit very little energy and effort to seeking information, in contrast, say, to seeking a fortune, a family, or a reputation. In fact, the truly explosive popularity of the World Wide Web as an information source may be due to the fact that the level of effort the searcher must engage in to find an answer to a question on the Web is at last so very little as to slip in under that minimal level of (least) effort that feels "natural" in information seeking. Most of the information that people eagerly seek online was once available in their local public or academic library, but the effort required to locate that information was seen as excessive in the vast majority of cases.

In the rest of this section, we will follow several IT innovations and consider their impact on information behavior research.

The first major technology in modern times to affect information seeking was the computer. Initially, its use for library information systems was limited—computers were used to capture machine-readable versions of library catalog records ("MARC" records), which, in turn, enabled the publication of computer-produced print-on-paper book catalogs. This was followed, in short succession, by so-called "COM cats," that is, computer output microfiche catalogs, which could update book catalogs between publications of paper editions.^[94]

It will be forgotten today that in the age of card catalogs, while in one library, one could not access the catalog of any other branch of the academic or public library, or of any other library, for that matter. In academic libraries, a comprehensive copy of all the materials on campus was generally available only in the main library.

Disseminating multiple copies of the full set of library records through book catalogs and COM cats in branch libraries was a significant, time-saving innovation.

These catalog innovations during the late 1960s and 1970s were followed by a true revolution in catalog accessibility—the online catalog, which was developed in the early 1980s. These constituted the first widely available end user information search systems, and much was learned about how untrained people did and did not succeed in this form of online searching.^[95,96]

For a variety of reasons, the card catalog structure could not be simply translated into online form. Questions of redesign of catalog access in the new context, and the development of new and faster system designs to improve access occupied many in LIS research over the next 10–15 years.^[97–99] (See also ELIS entry “Online catalog subject searching.”)

In the meantime, (at least) four other overlapping information-related revolutions were occupying the field as well. The first revolution occurred in the area of information retrieval, where various forms of automatic indexing and retrieval were experimented with over decades from the 1950s forward, gradually improving the speed and effectiveness of both retrieval and ranking algorithms.^[100,101] In the 1990s, search engines, such as Alta Vista and Google, drew upon these retrieval techniques to design their Web systems.

Second, in the early 1970s, online database searching was made practicable through searching against large databases on “dumb” (typewriter-like) terminals receiving and sending data over telephone wires. “Online searching” as then understood, and as then implemented by database vendors, was a complex skill that required considerable training to do well. Teaching these skills became an important part of LIS education and drew a lot of research interest as well. That type of searching required a mix of gifts that not everyone has, and numerous studies of online searching behavior resulted.^[88,102,103]

The third revolution was the development of the Internet and World Wide Web, which enabled access to information all over the world from anywhere in the world. We are still working through the many impacts and implications of this capability for all prior information technologies and sources of information.^[104–106]

The fourth revolution occurred with the widespread interest in creating digital libraries of all manner of textual and image material—and sometimes online portals to access those resources. The Digital Libraries Initiative in the 1990s marked the moment when, at last, truly substantial amounts of research money entered the information science field. Ann Bishop and colleagues addressed at book length the sociotechnical factors of digital library use.^[107] The new capability of storing and easily accessing previously unimaginably large bodies of information in digital libraries led to innovative experiments in the storage and use of primary resources materials.

Example studies are those of children using primary archival materials,^[108] uses of texts in the field of classics in a digital library,^[109] and use of a medical portal.^[110]

During the 1970s to the present, many studies of information behavior involved, to a greater or lesser extent, research on people’s use of and success with, these innovations in information access. On the whole, more behavioral research was done in the areas of online catalogs and online database searching than in information retrieval. For a long time, IR researchers were not particularly receptive to, or interested in, the human side of the equation, though in the 1990s they came to realize that people needed attention, too, in the overall effort to improve retrieval. See, for example, the contrasting emphases in the two entries in this encyclopedia by Salton (“SMART System: 1961–1976”) and Järvelin and Ingwersen (“User-oriented and cognitive models of information retrieval”).

With the development of frequent interaction with microcomputers in the early 1980s, the already-thriving field of human–computer interaction research (HCI) exploded and became a still larger field. HCI paid little attention to LIS research, however, and LIS paid little attention to HCI research, probably to the detriment of both fields. However, there may have been good reasons for this mutual indifference. The specific circumstances of needing and seeking information are not well understood, for the most part, outside of LIS, and required the focused attention of LIS researchers. At the same time, HCI researchers were working to discover general principles applicable to all online and computer access, and therefore tended to ignore the distinctive features of various “application” fields, including information seeking. (See ELIS article “Human–computer interaction for information retrieval.”) Perhaps the best blend of information science and HCI approaches to search user interfaces can be found in Hearst.^[111]

In this encyclopedia, Diane Nahl’s two articles on early and recent “User-centered design,” as well as articles by Elaine Toms (“User-centered design of information systems”) and Judith Weedman (“Design science in the information sciences”) address, in much greater detail, the efforts and results in this area at the intersection of information technology and the study of information behavior.

RANGE OF TOPICS OF INFORMATION BEHAVIOR RESEARCH

What have we learned over the years from the study of information-seeking behavior? This is a hard question to answer briefly, to put it mildly, but a description of the sequence of research topics of interest over the years may give a hint of the growing understanding over time of the human relationship with information. What follows is a mere sampling.

In the 1940s and 1950s, information seeking and gathering tended to be viewed implicitly as the study of the use of various forms of literature—books, journals, handbooks, etc.—and of various types of institutions and their services. How many books were circulated, how many reference questions were asked, how many people of what economic strata used the public library, and so on (see Berelson^[10]).

In the 1960s and beyond, studies of information seeking and use by the general public opened out the research to incorporate many sources of information, of which the library was only one.^[27,112] The first surprise was to discover how much information—in both personal and professional contexts—people got from friends and colleagues. In a study looking at how scientists' learned of things serendipitously, Menzel found that fellow scientists were immensely important in that process.^[113] In fact, in a large number of studies, the human preference to get information from other people was soundly demonstrated.

From early on, the dominance of the “principle of least effort” in human information seeking was demonstrated over and over.^[25] It may not seem surprising that people try to minimize effort in finding information, but the research demonstrated that ease of access and ease of use mattered more to people than the quality of the information they found. People have a (sometimes unjustified) belief in their ability to filter the good and valid information from the faulty, hence their tendency to undersearch to find the highest quality information available.

Further, information seeking is often quite unself-conscious. People are trying to solve problems in their lives, not “seek information.” Activities that involve information seeking are seldom differentiated from the other actions taken to solve problems. Good research design for the study of information seeking *must* recognize this reality; asking people what they have done lately in the way of information seeking is therefore not the way to get data with high internal validity, as a rule. Dervin has made this point repeatedly and insightfully. For a prime example of her research technique, see Dervin.^[114]

Thus, as a rule, people—even including Ph.D. scholars—develop what search skills they have incidentally to their primary efforts at research or problem-solving and often fail to develop a conscious repertoire of search skills and techniques to help them over difficult stages. Particularly among college students, discomfort regarding library research has been found to be severe enough to merit the term “library anxiety,” and a number of studies have been done on this topic (see ELIS entry “Library anxiety”). Along with the evidence of student difficulties with libraries, a large literature has developed on the goals and techniques of teaching “information literacy,” that is, the capability of finding and effectively evaluating desired information (see ELIS entries “Information literacy” and “Information literacy instruction”). In sum,

people often vastly underutilize available resources and are often quite inefficient in finding what they do find.

In the study of various academic disciplines, the close attention in the 1960s to the rich complexity of the culture of science enabled a subtler analysis of the information seeking in all the academic disciplines studied from the 1970s to the present time. See, for example, Patrick Wilson on the concept of “cognitive authority,”^[115] Julie Hurd on implications of information use patterns for library design,^[116] Paisley on “information and work,”^[117] Robert Taylor on “information use environments,”^[118] Cronin on invisible colleges (i.e., informal groups of researchers with shared interests),^[119] the model by Leckie et al. of information seeking in the professions,^[120] and Budd^[121] and Bates^[122] comparing the cultures of science and humanities. In the understudied area of archival resources, Barbara Orbach^[123] and Wendy Duff and Catherine Johnson^[124] have provided insightful descriptions of the use of historical archival materials.

During the 1980s and 1990s, several researchers deepened the understanding of various aspects of information behavior by exploring questions and areas previously not as well understood. Elfreda Chatman looked at the information environments of janitors, women in a retirement home, and prisoners.^[125–127] Cheryl Metoyer-Duran applied the concept of gatekeeping to five minority groups in Southern California and developed sophisticated (and sometimes counterintuitive) understandings about information flow within minority communities, and between them and the larger society.^[128] The challenge of studying unconventional groups and domains even extended to abused women^[129] and abused children.^[130]

Carol Kuhlthau is another researcher who has had very wide influence in the information behavior world. She developed a model of student information seeking, which she refined over several studies that are themselves models of the art of research. Her model runs counter to many assumptions in both education and library and information science about how people tackle researching a paper or project, and how that experience can be substantially improved over past approaches.^[131] Specifically, she discovered that the combined process of researching and writing a paper is complex and difficult for most people—indeed, the library research is inextricably bound with the understanding and gradual formulation of the thesis of the paper. Consequently, the simple idea of “picking a topic,” like picking an apple off a tree, then going to research it in the library, is not how the process reasonably can or should be expected to proceed. Yet generations of teachers and professors have left students floundering and frustrated as they moved, essentially without guidance, through this core process in paper-writing.

David Ellis' empirically based model of common actions associated with scholarly information seeking^[132] has also been influential, spurring several follow-on studies to test for similar activities in the work of people in

other circumstances. And, of course, Brenda Dervin's concept of "sensemaking" as a motivation for information seeking constituted the underlying model for much information behavior research.^[60]

In the 1990s and 2000s, along with the growth of the ISIC community, researchers expanded their look at information behavior by incorporating the whole environment—physical, social, and technological—in the study of people's interactions with information. Social context and social situation were recognized as essential to the understanding of information seeking.^[133,134] Karen Fisher (nee Pettigrew) developed the concept of "information grounds"—the joint creation of social environments by people in which to share conversation and information.^[135] Disciplinary examples of these rich analyses include science^[42] and business.^[136] As noted earlier, the study of "information practice," as a shaping paradigm for information behavior research, has emerged strongly in the twenty-first century.^[83]

Several recent studies have demonstrated particularly creative approaches to the study of children's information seeking, traditionally an underpopulated area of research. Virginia Walter demonstrated that children's information needs were immense and were in no way limited to requests made of school librarians!^[137] Joanne Silverstein studied unconventional forms of information use,^[138] and Ciaran Trace studied informal information creation and use by children.^[139] Research on the "information behavior of a new generation" is discussed in the recent book edited by Beheshti and Large.^[52]

During recent decades, a more sophisticated understanding has also developed of information genres and the ways they are shaped by practice. In a particularly elegant study, Kling and McKim showed how preexisting social information practices shaped the design of post-Web online information support in three scientific disciplines.^[140] Peiling Wang studied at the micro level how scientists actually make use of and subsequently cite other literature in the course of their research.^[141] Ann Bishop^[142] and Lisa Covi^[143] studied closely the interactions between people and the structure and genres of information.

CONCLUSIONS

Information behavior research has grown immensely from its scattered beginnings earlier in the twentieth century. We now have a much deeper and less simplistic understanding of how people interact with information. We understand information behavior better within social contexts and as integrated with cultural practices and values. The further complexity of information seeking through the use of various technologies and genres is coming to be better understood, though there is much more to be studied. In fact, even as I write, some six billion people are interacting with information

worldwide, drawing on cognitive and evolutionarily shaped behaviors, on social shaping and environmental expectations, and interacting with every information technology from the book to the wireless handheld "smartphone." There is unimaginably much more to learn about information behavior.

The state of our current understandings on these topics is reviewed in over 30 articles in this encyclopedia. See, especially, the section titled "People using cultural resources" in the topical contents list of the encyclopedia.

Information Behavior Models

Thomas D. Wilson

Publisher/Editor in Chief, Information Research, U.K.

Abstract

This entry outlines the development of models of information behavior. The concept of a *model* is defined and the different types of model are identified. Models of information behavior are presented within a typology of descriptive model, decision-based models, and causal models. It is suggested that, in research terms, a movement from descriptive models to causal models is needed if theory development is to take place in the field.

INTRODUCTION

Information behavior has been defined as

... the totality of human behavior in relation to sources and channels of information, including both active and passive information seeking, and information use. Thus, it includes face-to-face communication with others, as well as the passive reception of information as in, for example, watching TV advertisements, without any intention to act on the information given.^[1]

In addition to the specific aspects mentioned in that definition, we can add that the determination of information needs (or “information requirements” in information systems development) is part of information behavior research, as is the human interaction aspect of information retrieval (excluding, that is, the algorithmic work in the IR field), as exemplified by Ingwersen’s work referred to below.

The history of information behavior research has shown a move from the study of the information resources used by people, in an attempt by researchers to identify “information needs”, to the investigation of actual behavior in relation to information sources and systems. However, the situation is complicated by disciplinary and methodological divisions within the information disciplines, such that work in the information systems area is rarely put together with work in information science and, within information science, the human interaction aspects of information retrieval are rarely considered together with other aspects of information access and sharing. Much work in information retrieval also has a laboratory experiment basis, while information behavior research (at least over the last several decades) has been mainly qualitative in character, with the result that the two groups of researchers rarely interact.

To a degree, the interest in modeling information behavior arises out of a concern that these differences should at least be identified and recognized, in the hope that, as a result, gaps in research will be revealed and, perhaps through cross-disciplinary collaboration, explored.

MODELS

Definitions of models are numerous and include not only the *conceptual models*^[2] with which we are concerned here, but also physical models (such as those employed in architecture) and human models—the “model user” or “the model librarian.” All models, of whatever kind, are attempts at the representation, characterization, or exemplification of some aspect of reality or of human behavior. Models may be graphic, mathematical, or simply textual: we can describe a model in words, setting out, for example, a set of theoretical propositions. In this light, stating a set of hypotheses about a subject of investigation is to express a model of anticipated relationships among variables. We can also express those relationships in graphic form and, very often, in quantitative research the results of hypothesis testing are modeled graphically. Finally, we can express the same relationships mathematically, indicating the strength of relationships and again, a graphic model of the results of hypothesis testing may also show the strength of relationships. Mathematical models for weather forecasting, for example, will employ huge amounts of data in complex equations of relationships among many variables, but some mathematical models are quite simple in construction: $E = MC^2$ is a simple equation, modeling the relationship between energy, mass, and the speed of light, with enormous implications.

There are also pseudo-mathematical models (i.e., those for which units of measurement are lacking), which attempt to say something about relationships in information science, the most cited of which is that by Brookes,^[3] $K(S) + I = K(S + \Delta I)$. This is simply a more concise way of saying that a new “knowledge state” $K(S + \Delta I)$ is brought about by the addition of information (I) to the existing knowledge state ($K(S)$).

The use of models of these different kinds is as old as scientific endeavor: indeed, geometry itself can be seen as a system for modeling spatial relationships. In astronomy, certainly from the time of Kepler and Copernicus, models

of the planetary system, and their representation, subsequently, in the physical model of the orrery, have been commonly used. The same applies in the social sciences, particularly since the introduction of system approaches to social phenomena and, from the social sciences, models, particularly graphical models, have found their way into information science. Case's^[4] treatment of models constitutes a valuable supplement to the ideas presented here.

MODELS IN INFORMATION BEHAVIOR RESEARCH

In information behavior research, the word *model* is generally used to describe graphical models: diagrams that express actual or theoretical relationships, or ideal processes of interaction with information. The common elements of such models are the information user and his or her environment or context, the information resources available to the user and the "tools" available (which may include various levels of technology, or, for example, a human intermediary). Inevitably, therefore, because they all attempt to portray the same phenomena, the various models are very similar and, to a large extent, map on to one another.

It is noted above that models probably found their way into information science from the social sciences, and this may well be the case for the behavioral aspects of the subject. However, in other fields, such as bibliometrics and information retrieval, mathematical and pseudo-mathematical models have also been used.

We find three kinds of models in information behavior research: the first is the purely descriptive, which sets out the connections between user, tool, and information

resource, showing the general communication flows among these elements. Wilson^[5] set out a very generic model of this kind (Fig. 1), which, in spite of changes in the technology between 1981 and the present, can still be used to outline the connections.

This kind of model simply maps out the actions that an information user may engage in to obtain or exchange information, as indicated by the lettered lines: thus, one strategy is indicated by lines f, g, j—an information user seeks the help of an information intermediary, who uses the available technology to access structured information resources. Clearly, in this kind of diagram not all of the lines of communication can be shown without making the diagram virtually unreadable: thus, in this diagram no feedback lines are shown, which would indicate, for example, what happens when information is found or fails to be found.

The model suggests that information seeking can be seen as the interaction of three "systems": the user in his or her life-world and in particular groups in that life-world, with the "reference group" shown to illustrate this notion; the information systems that mediate access to information resources (either used directly by a person or by an intermediary acting on behalf of that person); and the system of information resources, accessed through the information system or directly, for example, in the case of the person browsing library shelves. The whole is shown to exist in a "universe of knowledge," implying that the individual may access other information resources, which are not organized, such as using direct observation of phenomena, or talking to other people. There is no suggestion in Fig. 1 of any limitation of the model to work life or ordinary life, it is sufficiently general to cover both: Savolainen's^[6] model of everyday life information

Fig. 1 Information seeking—a generic model.

Source: From Wilson.^[5]

seeking elaborates the left-most set of “nested” circles in that particular context, drawing upon sociological theory in a more explicit manner.

We might label models of the kind shown in Fig. 1 as models of “what can be done” in seeking information. Such models are not generally theoretical in character, although theory may inform their construction; thus, reference group theory^[7] clearly informs the model and the use of the term “life-world” suggests a phenomenological orientation, since this is a term derived from that field.

The second type can be characterized as models of “what happens.” Such models, of which Fig. 2 is an example, have more the character of decision diagrams, showing alternative courses of action and, in some cases “if A then B” situations.

This kind of model makes some things more obvious than models of the kind shown in Fig. 1: it brings in the notion of success or failure to find information, identifies “information sources” as formal or informal (“information systems” and “other information sources”); it brings in “information” use and the idea that use may or may not lead to the satisfaction of the initial “information need.” Again, theory is not explicit in the model, but “social exchange theory”^[8] has influenced the model in the notion of “information exchange” to show “other people” as sources of information.

Clearly, more lines and more detail could be provided in this model; for example, by showing that a need for information does not always lead to information-seeking behavior, or that a failure to find information does not necessarily lead to a further round of information seeking. However, more boxes and more lines may only serve to confuse and one of the advantages of simple graphical models is that they are easy to understand and the lack of

detail allows the reader to think further about what appears to be missing and what further relationships might be embodied in the diagram.

The point that all models of this kind map on to one another can be illustrated by reference to the model by Krikelas,^[9] which has similarities to Fig. 2. However, Krikelas introduces the notion of ‘deferred need’ and specifies ‘memory’, ‘personal files’ and ‘direct observation’ as ways of acquiring information that would be subsumed under ‘demands on other information sources’ in Fig. 2.

Models with a rather similar intent include those of Leckie et al.^[10] and Byström and Järvelin.^[11]

Models of the second type are concerned with the individual information-seeking process and probably the best known of these is that proposed by Kuhlthau,^[12] which is not usually expressed graphically. However, Kuhlthau does provide a graphic model which associates the stage process of information searching, the feelings experienced by the information seeker, the cognitive dimension and the actions taken (Fig. 3).

An important aspect of Kuhlthau’s model is that it is based on theory: thus, the stage process is derived from theories of the construction of learning by Dewey, Bruner and Kelly [12, Ch. 2]. This recognition of the role of theory distinguishes models of this kind from the first type.

Wilson’s^[13] “problem solving” model is, similarly, a stage process model: however, it is based not on stages of the search process but on the stages in coping with a problem. Thus, it hypothesizes a four-stage model, problem recognition, problem definition, problem resolution and solution statement, and associates the need to seek information with these stages (Fig. 4).

Fig. 3 Kuhlthau's model of the information search process.

Source: From Kuhlthau.^[12]

Rather being derived from theory, this model states a theory: that in the course of solving a problem and delivering the solution, the individual's state of uncertainty on how to proceed is resolved by information seeking. It is a modest theoretical statement but, like Kuhlthau's model, serves to associate information-seeking behavior with a more general phenomenon. The information-seeking element is not specifically shown in Fig. 5, but the paper notes that uncertainty is resolved through information seeking and use and the figure could be modified to show this.

A third example of models of this kind is Ingwersen's^[14] (Fig. 5) which draws upon cognitive psychology and the idea of mental models as a way of indicating the cognitive processes involved in information searching.

Within this category of models, a slightly different perspective is offered in Wilson's model of 1996 (Fig. 6), which is based on his earlier models: the top level of this model is a simplified version of one of the 1981 models, which is then expanded to indicate the demographic and other variables that influence information seeking, the different modes of information-seeking behavior and theories that may be of explanatory value.

Thus, "stress/coping theory" from the health field^[16] is suggested as possibly explaining why some people seek information in response to a problem situation while others do not. For some, the stress created by the "need to know" is not strong enough to overcome the barriers (represented here as "intervening variables") that must be overcome, actually to engage in information seeking.

Choo^[17] has produced a model of this kind which seeks to integrate a number of ideas from research on information behavior. Fig. 7 presents three connected triangles:

the top triangle shows the circumstances of information need, while the bottom two triangles show, respectively, purposive information seeking and information use. Choo notes the complexity of the situation regarding information use, commenting:

How this information is processed and put to use depends on the cognitive style and preferences of the individual, the emotional responses that accompany information processing, and the organizational or social context surrounding information use.

He goes on to use the model to illustrate organizational information use, and its shortcomings, in the *Challenger* and *Columbia* space exploration accidents, showing how gaps in understanding and false shared beliefs contributed to the tragedies.

Finally, there are a limited number of causal models, that is, models that seek to demonstrate not only the processes of information seeking or the relationships of this behavior to other phenomena, but that attempt to show causal relationships. A very generic model of this kind is that of Johnson,^[18] which suggests causal relationships in cancer-related information seeking (Fig. 8).

Johnson's model appears to say that demographic characteristics (such as age, sex, and ethnicity) and direct experience of the phenomenon about which information is sought, together with the perceived importance of the search problem and the individual's beliefs about the problem determine the utility of the information "carrier" (source would be a more common term in information science) and these "utilities" together with specific

Fig. 4 The problem-solving model.

Source: From Wilson.^[13]

Fig. 5 Ingwersen's cognitive model.
Source: From Ingwersen.^[14]

characteristics of the source determine the information-seeking actions the individual will carry out.

It can be seen that Johnson's model is much more concerned with the motivations for information seeking (the background factors and the personal relevance factors) than with the specific operations of information

seeking, whereas the models proposed by Krikelas and Wilson are more concerned with the latter.

Finally, in this section, Höglund et al.^[19] proposed a theoretical, causal model of the relationship between information and trust in health care. The model was derived from previous research on health information and

Fig. 6 Wilson's expanded model.

Fig. 7 Choo's model of information needs, seeking and use.

Source: From Choo.^[17]

on trust in health care and the test of the model was carried out on a large database of responses to a Swedish national survey (Riks-SOM). The model (Fig. 9) links health status, contact with health institutions, library use, Internet use, and trust in health institutions, variables that were explored in the survey. The study is an example of how large data sets can be used for secondary analysis.

There appears to have been a loss of interest in the idea of modeling information behavior between the early models of the 1980s and those from the mid-1990s onwards. Certainly, since the publication of Wilson's review in 1999, interest has revived and the development, modification, and testing of models has become a significant area of research in the field.

Source: Redrawn from Johnson.^[18]

Fig. 9 A model of trust in health care.

Source: From Höglund et al.^[19]

For example, Godbold^[20] has evolved a model which seeks to marry Wilson's models with Dervin's^[21] concept of "sense making." Godbold proposes that information seeking can be seen as a multidirectional activity, rather than a mono-directional activity, and this also appears to be the thrust of Foster's^[22] "nonlinear" model. Ingwersen and Järvelin^[23] have also developed a general model of the information-seeking process within an overall cognitive framework. This appears to be a generalization of

Ingwersen's earlier cognitive model (discussed above), with the organizational, social, and cultural context given greater prominence. The international interest in modeling is shown not only by those mentioned earlier in this paragraph (which come from Australia, the U.K., Finland, and Denmark) but also by Niedzwiedzka's^[24] "proposed general model of information behavior" from Poland. Like Godbold, Niedzwiedzka begins with Wilson's 1996 model and expands it in an attempt to incorporate aspects of

Fig. 10 Niedzwiedzka's general model of information behavior.

Source: From Ingwersen and Järvelin.^[23]

information behavior other than information seeking. The result is a kind of combination of Figs. 1 and 2 in this entry (Fig. 10).

CONCLUSION

The three types of models discussed above demonstrate a movement from models of activity, which are generally descriptive, through those that link information seeking to other aspects of behavior or to characteristics of the information user and/or information sources, to those that embody hypotheses about relationships. From the point of view of the genuine development of research in the field, it is desirable, even necessary, that this movement should take place. One can only go so far in refining descriptive models and even those that embody theory can only progress if the underlying theories are tested, and it is the function of the third type of model to graphically illustrate the postulated theoretical relationships. It is hoped that the sustained level of interest in research into information-seeking behavior will now move away from the refinement of descriptive models and on to the development and testing of theory.

Information Crises and Crisis Information

Philippe Baumard

School of Engineering, Stanford University, Stanford, California, U.S.A.

Abstract

Information crises are failures of sense-making in organizations, i.e., failures to attribute a meaning and interpretation that can lead to a corrective action. Challenging the hierarchy of data, information, and knowledge, this entry argues that information crises cannot be resolved through normalization and normative prescriptions, but rather by the reinstallation of behavioral-involvement mechanisms, that have been lost in electronic mass-intermediation of postindustrial organizations.

Postmodern societies are highly dependent upon various forms of information, because most of their technical, societal, social, and economic subsystems are consuming as much information that they produce. The rise of machine intermediation has contributed to a lag in the speed and accuracy of human sense-making. By 1999, most experts agreed that machine-to-machine communications could not represent more than half of world traffic before the 2020s. This figure was reached in 2008. Information mostly circulates from machines to machines, from onboard plane maintenance systems to computers on the ground, from an Internet server to a home desktop, from a financial transactions platform to a trader's desk.^[1]

One consequence of such an acceleration of information diffusion lies in its autonomous development. Society and local societal organizations rarely possess the mechanisms to influence, forbid, or shape its diffusion. In archaic, and then modern societies, access to information was conditioned, with conditions being the societal strata of groups and communities. But now information is fairly accessible to everyone. The rise of electronic communications, and in particular of the Internet in the late 1990s, has reduced the distance and privileges in accessing, producing, discussing, or emitting information. Machines handle half of the world's communication traffic, and the other half, although not fully automated, has reached an unprecedented level of reliability, not from a sense-making perspective, but from a transmission point of view. The latter half suffers none or few denials of access. While this status has produced tremendous learning opportunities for populations deprived of educational infrastructures, it has also produced on one hand, informational crises, and on the other hand, crisis information management issues.

Informational crises are situations where the opinion-makers, the stakeholders, the potential victims, the organizations, and the policymakers find themselves fully or partially incapable to give sense to critical problems. Plato, in his *Theory of forms*, already addressed what would otherwise seem a contemporary issue. For Plato,

universal nature (*phusis*, φύσις) is embodied into recognizable forms or bodies (*sōmata*, σώματα), which are merely mimetic of their real existence. In other words, information would only be a somatic expression of the likeliness (*mimēmata*) of a real existence. Modern assumptions on the definition of information follow Plato's intuition: Information is seen as a state of a system that becomes formalized through sense-making, i.e., attributing a message to a given information. Informational crises, in a Plato perspective, would hence be situations where somatic expressions of an event overwhelmed sense-making, either because a recognizable pattern or form cannot be attributed, or because any reliable meaning can be attributed to each individual mirror that compose the information source.

While Plato was trying to understand how mankind accesses nature, modern informational crises have penetrated most societal arenas, from healthcare, politics, and economics to the conduct of business and welfare. Stock markets are dependent upon a mass of information that clearly surpasses the human limitations of sense-making, with or without the support of modern information technologies. Military operations are intertwined with a global information infrastructure that leaves no place hidden from public scrutiny, no rationale unquestioned, and no legitimacy freed of questioning. Dissymmetry of the weak defending against the incumbent makes an intensive use of deliberate information crises, aimed at challenging the rationale, the legitimacy, and the morale of its offensives. One defensive mechanism, not unknown to nature and biological systems, is to develop forms, or information strategies, that defy the larger opponent's sense-making, and hence creates a somatic state within its ranks. Such deliberate informational crises are called "asymmetric campaigning."^[2] As organizations are more and more dependent on information for the continuity and stability of their operations, they also become more vulnerable to information crises, either genuine, or deliberate for the purpose of their destabilization.

Information crises, and crisis information are, therefore, very close concepts. While crisis information represents the attempt to make sense of a crisis with the purpose of solving it, information crisis represents the state in which organizations are prone to engage in crisis information. One immediate issue relates to sense-making. Attributing sense, i.e., producing a message derived from information, relies on a continuous and ongoing retrospective analysis of plausible forms that attempts to rationalize events and people's actions (p. 409).^[3] The first obvious assumption is that to make sense, people or organizations must first notice the concerned events. What people notice or do not notice is not, however, a matter of access, presence, or availability of data and information. Information becomes accessible when one is able or capable of understanding its meaning. When we fail to notice, we might simply fail to understand. Stimuli often do not escape our attention, they escape our sense-making. As R.D. Laing puts it: "The range of what we think and do is limited by what *we fail to notice*. And because we fail to notice that we fail to notice, there is little we can do to change, until we notice, how failing to notice shapes our thoughts and deeds" (quoted by Goleman (p. 24)).^[4] An informational crisis is often a sense-making crisis, rather than being a problem of availability or quality of the information at hand.

THE MECHANISMS OF INFORMATION CRISES

Information crises grow on the grounds of uncertainty, independently of the nature, the depth, and the reliability of the information at hand. Both the Columbia and the Challenger space shuttle accidents created long and painful information crises, despite dealing with some of the most documented industrial and engineering processes on earth. In contrast, the impossibility to give sense to an event can occur with a very little, ill-mastered information. The development of viruses such as H5N1 or SARS is exemplary: the lack of information about viral behavior creates the information crisis. Hence, many information crises are triggered by a failure to conduct a reductive analysis, either by too numerous interpretations being available and creating causal ambiguity, or by the impossibility of reducing reality and making it stay real (p. 327).^[5]

The first conundrum of such a principle lies in knowledge ontology. R.D. Laing's philosophical pun says that knowledge turns in circles, for its substance can only be accessed through teleological means. Data can produce information with a mindful purpose. And knowledge can be derived from information, assuming that the sense that we gave to the data and information has not been filtered by our perceptual biases. But previous knowledge is what biases our perception and the way we select information in the first place. Hence, information crises encompass both the previous learning and knowledge of concerned individuals, as well as disconcerting new information. Crises

arise when individuals are no longer capable of "labeling and categorizing to stabilize the streaming of experience" (p. 411).^[3] This situation can either arise from events that an individual has never experienced before, thus depriving them of labels and categories of reference, or from new stimuli coming through familiar channels, but that do not match the existing labels and categories.

The central mechanism of an information crisis is therefore one of imperfect, incomplete, and/or unreliable interpretation. The lack of reliable interpretation has three main sources. First, individuals themselves tend to distort their perception, more or less purposefully. Following Plato, if we accept the idea that information precedes a somatic expression of reality, then traumas, guilt, fears, and pain can lead an individual to see what he or she wants to see, instead of what is presented.^[4]

Second, organizations replicate, duplicate, and distort individual distortions, for they reflect collectively the more or less somatic reading of information conducted by individuals. "Those interpretations are generated within the organization in the face of considerable perceptual ambiguity" (p. 19).^[6] As Starbuck puts it (p. 91):^[7]

Most of the time, organizations generate actions unreflectively and non adaptively. To justify their actions, organizations create problems, successes, threats, and opportunities. These are ideological molecules that mix values, goals, expectations, perceptions, theories, plans, and symbols. The molecules form while people are result watching, guided by the beliefs that they should judge results good or bad, look for the causes of results, and propose needs for action.

Far from being a distinctive reality on which action is acted, information is an integral part of generated action. Information may be generated ahead of time to justify an intended action, and vice versa, information is often generated ex-post to justify a non-intended action. Of course, this production of information does not flow in two separate categories, so people in organizations cannot really tell if information has preceded or followed an ongoing action.^[3]

Third, information itself can be destructive. Destructive information can be defined as a set of messages, signals, and stimuli that mislead cognitive and behavioral routines of an organization, and lead an organization or an individual to generate confusion. It also threatens the reliable pursuit of the organization's goals. Goffman, in his study of interaction rituals between individuals, detected such a phenomenon (p. 141),^[8] by observing individuals purposefully distorting information to manipulate and mislead others. Others have described destructive information as "guilty knowledge" or "dirty data."^[9] Incomplete, truncated, uncertain data can lead individuals to encounter sharp crisis situations, which are either solved by the production of reliable data, or, if not solved, can exhaust reductive analysis, morale, and determination.

Hence, information, or the lack of, can produce decision paralysis, panic, fear and through somatic and secondary effects, and actual pain. While this phenomenon is well-known to the art of medicine, few studies have been conducted in organizational settings other than healthcare and patient safety.

SPIRALING, AUTO-FEEDING, AND SELF-REINFORCEMENT

Sense-making is about presumption. It is social and systemic (p. 412).^[3] Presumptions are the products of past experiences, social learning, and education. In nature, presumptions are born through interactions and propagate through interactions. When people face an information crisis, they usually seek help in their immediate surroundings, engage in collective sense-making, seek information in the press, on the internet, try to reinforce their core beliefs to fight disturbing stimuli.^[4] They engage in socializations that can reduce their anxiety and the uncertainty surrounding the situation, or reinforce both the uncertainty and the importance given to their interpretation of the new event. This second phenomenon is known as “sense-making spiraling.” Seeking help from a knowledgeable source can definitely reduce uncertainty when the lack of knowledge is dissymmetric. When ignorance and incomplete information are mutual, with little expectation to add sense to the ongoing information crisis, individuals provide feedback loops to each other that ignore better-informed sources and may aggravate the situation.^[10,11] Over time, these processes trigger more negative outcomes, and turn into vicious cycles, leading to a spiral of counter-productive influences auto-feeding with incomplete information.^[12] These deviation-amplifying loops are well-known to the Internet, in a modern version of rumors, grow shorter, more concise, easier to grasp, and to tell as they travel from one individual to another.^[13]

As individuals tend to associate the repetition of information as a sign of its reliability, the Internet with its continuous flow of commentaries and self-produced knowledge has become a vector of crisis information vulnerability. Duplication, however, is not to be blamed on individuals, but on society’s evolution as a whole. The press, facing an intensive competition from free media, is also forced to outsource most of its information, and therefore often engages in commentaries driven from secondary commercial sources. The cost structures of the press have thus evolved from mostly primary information at its birth, to mostly secondary sources and commentaries in its maturity phase. The process of validating information has become tedious, as competition forces editors and media organizations to deliver news almost instantly. Moreover, the rise of a press deriving benefits from sensational information has progressively blurred the boundaries between institutional and legitimate sources of information and

their look-a-likes. With the rise of electronic intermediation, most people in organizations access information faster through external electronic media than through internal channels. Hence, crisis information spirals are not per se an organizational phenomenon.^[14]

Contrary to the phenomenon of rumors, however, people in organizations rarely generate destructive information spirals intentionally. Most informational behavior in organizations is somewhat “positional,” in Hirsch’s terms.^[15] People seek to gain information that allows them to position themselves, reduce ambiguity, and get a perspective that they perceive as slightly better than those their own or than what they witness in their colleagues. Accordingly, people do not see information as having absolute superior value, but rather an immediate, practical leverage for their ongoing actions. Rather than challenging information being used and articulated in ongoing programs, people favor collateral and ad hoc organizations, which would leave their main programs untouched, and their deeds unchallenged.^[16] Secrecy that can turn banal information into highly destructive information follows a social psychology that is more embedded in ignorance than maliciousness.^[17] Human inferences are imperfect, and turn genuine interpretations into misleading and contaminating shortcuts.^[18] Moreover, most information is unconsciously processed by individuals, so that people are generally not able to identify how they gathered, assimilated, and transformed information that leads their actions and deeds.^[19] Hence, individuals rarely discriminate between genuine information and its many doubles. Reality is taken for granted, until proven otherwise. Artifacts are as much instrumental as reality, for realities are known as genuine only when they get dismantled.^[20] This latter characteristic of informational behavior contributes to sustaining the development of crisis information spirals in most organizations. “Information-generating” behavior is much alike the “action-generating” behavior described by.^[7] People generate information while listening upwards; they document *ex post facto* an action-generation whose rationale they might have lost; they fine-tune their past commitments with the new criteria for approval; they reuse uncompleted achievements that have bred frustration and translate them into the new set of core beliefs.

This leads us to the most puzzling characteristic of crisis information: its self-reinforcement and its capacity to feed on itself. Findings in action-generation suggest that the pursuit of programmed behavior is strongly intertwined with the self-reinforcement of an information crisis. Individuals produce learning and information by repeatedly experimenting successfully with behaviors that they turn into programs. When an action fails to produce the expected outcomes, they can either modify the behavior to alter its output, or alter the information so that their unchanged behavior matches the discordant informational output. Large banks and financial institutions have suffered such a phenomenon repeatedly from the early 1980s

till today. A trader engages in hazardous investments, realizes that their outcome does not match his or her expectations, and subsequently modifies the informational output with complicities that would prevent a behavioral change, in expectation of a positive reversal of fortune.

Self-reinforcement is often accentuated by group behavior. Janis^[21] described how small groups facing crises tend to protect their cohesiveness through collective rationalization, stereotyped views of out-groups, self-censorship, illusion of unanimity, and self-appointed “mindguards.” Different from spiraling, “groupthink” aims at protecting the group from a perceived vulnerability, by reaffirming the shared core belief, and developing an illusion of invulnerability. The immediate consequence of groupthink is the cessation of search for alternative interpretations. Group members discount early warnings, and sanction peers who would question the group cohesiveness by doing so. Historical cases discussed by Janis^[21] include the attack of Pearl Harbor and the Bay of Pigs crises.

RESOLVING INFORMATION CRISES

Resolving informational crises often involves managing the crisis itself. A crisis is a situation that seriously threatens an individual or an organization. As the etymology of its noun suggests, a crisis is a time for a decision. Crises, however, are usually unnecessary. There is no scientific evidence that crises improve or diminish organizational longevity. There also is no evidence that organizational survival indicates effectiveness (p. 54).^[22] In fact, most organizations keep their names to maintain the continuity of their recognition by individuals who deal with them. But most organizations have little to do with their constituents from a decade earlier. Two questions come immediately to mind: if escaping crises does not display any form of correlation with resilience, other than psychological at the individual level, and if organizational survival is not an evidence of their performance, why do organizations continue to manage crises? Why do they not simply leave the environments that created the crisis in the first place?

An answer comes from Staw et al.^[23] under the form of threat-rigidity effects. Perceived uncertainty over anticipated events creates slower decision-making, and organizational rigidity, that are often accentuated by groupthink at senior management levels.^[21] Accordingly, organizations persist in managing crises because they believe they can repeat their past successes; they want to protect this core belief; they do not want to disavow public commitments, and hence, most often end up escalating their commitments, not to the crisis itself, but to its resolution process. This phenomenon is not completely a stranger to Plato's intuition: information crises are somatic expressions of an inaccessible reality; hence, organizations focus

on the symptoms that are immediately accessible and actionable. But as Nystrom and Starbuck p. 55^[22] underscore: “In real crises, weathering-the-storm strategies work only briefly. Then the symptoms of trouble reappear; only this time, the organizations start with fewer resources and less time to act.” Not surprisingly, crisis information management techniques are sometimes more somatic and symptomatic than the crises themselves.

Symptoms of crisis information management that ultimately aggravates the crisis include an over-emphasis on prediction (as an attempt to reduce uncertainty), mindguards and preachers of hierarchical control (expected to bring back a sense of control), and increased demands for various rationalizations and justifications (as an attempt to analytically exhaust reality). These three “usual suspects” of inadequate crisis information management are grounded in one solid block, made of five interlocked components: the reproduction of past successes; the defense of legitimacy and legacy of concerned decision makers; preparation for potential scapegoating; the reassurance of the null hypothesis; and the evaluation of senior managers.

Firms try to reproduce their past successes, by approximating their mechanisms and re-enacting environments that approximate the conditions of the past. One obvious rationale lies in mass assets effects, and the attempt to reemploy past expertise into new lines of products and services. That is to say, firms tend to bend environmental conditions so as to fit already deployed assets on a global scale. Over time, this mass asset impact prevents firms from assessing the validity of their learning. They enact environments that tend to self-validate their learning, eventually masking vulnerabilities or misconceptions. A less obvious consideration is that firms try to “do more of the same thing,” while adapting to unexpected demands through management by exceptions. Alas, environments of the past are not replicable in the present. While this seems obvious, most organizations develop over time the core belief that efficiency and consistency of successes achieved in the past are replicable in environments that have little to do with the earlier economic, technological, and societal conditions. Hence, usual mismanagement of crisis information is rooted in the belief that trying to replicate conditions of the past will increase the capability of prediction over the present. Unfortunately, learning from repeated success makes future failure very likely.^[24]

The second “usual suspect”—i.e., increasing hierarchical control—is mostly grounded in the criteria that are used to assess, reward, or sanction senior managers. People in organizations are judged on one hand on their past legacies, and on the other hand, on the institutional “soundness” of their decision process. Past legacies are made of past successes, but also of past difficulties and the way they were handled. Immediately increasing hierarchical control in a time of crisis presents the advantage of clearly identifying the ownership of the crisis, and

eventually, the lack of ownership of the concerned senior manager, if events transform into a real disaster. Hence, an increase of hierarchical control is often a strategy that prepares for potential failure of the crisis management, prompting potential scapegoats, and preparing a defense of probably questioned legitimacy.

The third “usual suspect”—i.e., analytically exhaust reality—has more to do with the search for a reassuring absence of change, and the protection of core beliefs. Not all crises express themselves loudly, and organizations are prone to errors of appreciation. As it might be unclear whether the information crisis at stake may end up in a success or a failure, organization members usually slant interpretations to argue that nothing has really changed in the practices or the behavior of employees. Unfortunately, employees often think along the same lines and are not really willing to share information about mistakes they have made. The consequence is that the sought “null hypothesis” is easily achieved. Senior managers duly question all middle-managers and employees asking them if they had wrongly changed constituents that might have led to a crisis, and the employees and middle managers duly answer that they did not. Paradoxically, this exchange of tense and polite audits is mutually beneficial, by contributing to escapes and scapegoating strategies by both employees and senior management. Accordingly, managers tend to dismiss small failures that challenge the firm’s foundation premises, perceive errors as small deviations and experiments, and prepare the ground for justifying that a large failure is fully exogenous to both their management responsibility and their governance techniques.^[24]

As discussed earlier, information crises, and information about crises, are primarily failures of interpretation. Not surprisingly, organization members attempt to reinforce their sense-making in the most controlled and predictable manner. But when information has lost its labels, senior managers attempt to invent new ones or force data into old repositories. And while the experience has been destabilized, and the labels left untouched, managers are convinced that relabeling will improve experience. Yet when channels have been unchallenged, and the crisis still occurs, managers ask people to justify once again that they used the same channels as usual. As Nystrom and Starbuck (p. 55)^[22] put it: “They know that their current beliefs and procedures have arisen from rational analyses and successful experiences, so they have to see evidence that these beliefs and procedures are seriously deficient before they will even think about major changes.”

Crisis information management is about stopping the self-reinforced and auto-feeding phenomenon that surrounds a crisis, and is made of fears, anxiety, rumors, and apprehension about being misjudged. By increasing management control and hierarchical scrutiny, managers often “de-humanize” the crisis and the information surrounding it. Accordingly, people who feel that they need to justify

unintended actions with unintended consequences also perceive a growing distance between them and the people asking the questions. Crises are not systemic. On the contrary, the existence of a crisis explicitly expresses that both the social and the management “systems” have failed to absorb an environmental change. To reapply and reenforce a system that just failed is “doing more of the same thing,” i.e., trying to solve an information problem by substituting the same information under another “form,” to quote Plato’s expression. Increasing control, demanding facts and figures, are somatic responses. They express a mimetic symptom that does not suppress, but rather leverages the original expression of the soma.

In their seminal study of modern crises,^[2] Atkinson and Moffat surmise that the rise of information-dependency in modern organizations led to the generalization of “nonlinear dynamics” as a principal, not a peripheral component of organized societal life (Table 1). Atkinson and Moffat (p. 184),^[2] reflecting on the organizational roots of the Columbia Shuttle Accident, infer that

within the rule-based and hierarchical safety control system, information was being lost. The right information existed, but within the almost tangential network of unofficial e-mails, exchanged on a trust basis by engineers and scientists working alongside, but outside, the hierarchical control chain. Truths established by NASAs scientific and engineering networks were not getting through to those who needed them, crucially to those who needed, even if they did not want, to know.

Reflecting on the Challenger Shuttle accident, Weick (p. 397)^[25] suggests another characterization of the role of information in crises. Reviewing Diane Vaughan’s works on the Challenger accident, Karl Weick notices: “The O-rings were not the only problem with the connecting joints. Rainwater had accumulated in joints on an earlier launch (p. 304), and the putty that was supposed to prevent hot gas from even reaching the O-rings had repeatedly failed (p. 10).” Where Atkinson and Moffat are describing an institutional malformation of modern organizations,

Table 1 Characteristics of complex nonlinear organizations.

Complexity concept	Information age organizations
Nonlinear interaction	The organization is composed of a large number of nonlinearly interacting parts
Self-organization	Local coevolution induces long-range order
Nonequilibrium order	Interactions within the organization proceed far from equilibrium. Correlation of local effects is key
Collective dynamics	Cascades of local effects ripple through the organization

Source: Adapted from Atkinson and Moffat.^[2]

i.e., the spreading of uncontrolled electronic communications, Weick sees elements that

speaking to larger issues of the role of chance in organizational outcomes, distraction during moments when embedded signals of danger come across one's desk, credibility as a function of position, and organizational learning in the face of shifting attributions and incomplete data (p. 397).

In other words, the rapid growth of signal-detection opportunities, sensors, and electronic devices in organizations does not seem to improve its sense-making performance, but rather multiplies the number of nonlinear interactions, nonequilibrium orders, and noninteracting or interacting nonlinear parts.^[2] Table 1 from Atkinson and Moffat's study of modern crises and insurgencies, illustrates characteristics of postindustrial organizations as envisioned by the authors.

The multiplication of interpretations in organizations is not a new phenomenon, and in a sense, an organization cannot be anything else than the permanent re-combination of random nonlinear interactions. What is new is the loss of correlation between power and social structures and information life in organizations. Whereas information has been subdued and submitted to preexistent and prevalent authority structures for centuries, it is now able to circulate beyond hierarchical boundaries, bypassing legitimate chains of command, for better or for worse. As Karl Weick noted about the Challenger disaster, "in 1985 there was both escalating concern about safety and belief that risk was acceptable, an unusual combination of simultaneous belief and doubt that may be more common than we suspect" (1997: 398). The main difference between Von Braun's NASA in 1951 and the modern NASA in the twenty-first century is that deviance has been heard; not acted upon, but heard beyond the institutional and legitimate boundaries of the organization. The "normalization" of events^[26] that used to be a long and maturing process of many social interactions, is now attempted to be achieved by an uncontrollable nonlinear and quasi-instant process of electronic messaging. However, in such a substitution process, involvement is replaced with figuration; facing issues is replaced with declarative safety nets, as noted by Atkinson and Moffat,^[2] Weick,^[25] and Vaughan.^[26] Such attributes are symptomatic of postindustrial organizations. Huber^[27] suggested that such organizations "rely upon all available knowledge, always more knowledge," that they must face "complexity, always more complexity" and "turbulence, always more turbulence." They must make very complex decisions, which require "the consideration of an ever-increasing number of variables with ever more complex relationships between them" (1984, p. 933). From this foundation, George Huber then considered the effects of the advent of new information technology, concluding that "postindustrial organizations will be more formal,"

and that "the acquisition of information will be more directed, more integrated, and specialized" (1984, pp. 933–943). While Huber's premonition proved accurate in most points, a third sequel of postindustrial organizing has been overlooked: postindustrial organizations are not only prone to informational crises, they generate them.

Information Explosion

Ronald E. Day

School of Library and Information Science, Indiana University, Bloomington, Indiana, U.S.A.

Abstract

This entry discusses the concept of the information explosion as an empirical phenomenon and, more so, as a discursive concept. The term is discussed in relation to discourses on the information society and in relation to the concept of information overload.

Within its concept the term “information explosion” most often refers to the extended and largely continual growth and proliferation of “information” (newspapers, books, journal articles, television programs, Internet Web sites, e-mail, radio programs, etc.) during the nineteenth and, particularly, the twentieth and now the twenty-first centuries. It is a term that is central in discourses that demand information management in response to social, institutional, and even personal information growth and proliferation. It is often associated with other terms, such as “the information society” and “information overload,” which mark some qualitative social and historical event arising out of these quantitative increases.

The term characterizes the growth and proliferation of data, documents, and communication in both general social and in scientific communication. With such a broad sweep, the term signifies a general cause that demands greater information management across an equally broad sweep of informational forms: bibliographic and other documentary forms; abstracts, catalogs, and other records of initial documents; informal or “grey” literature in the sciences; scientific data; internet and broadcast media. The “information explosion,” broadly conceived, brings within its domain much of what we experience in, and as, modernity, and from this viewpoint it may be seen as what has allowed local lives to be understood as global issues, as well as has allowed for the observation and even surveillance of individual lives through national and international agencies. Indeed, any discussion of the “information explosion” would be addressing some of the major social challenges of information management and evaluation in modern societies across a broad range of areas: national intelligence and many other governmental and social policy issues; social and cultural values and welfare; scientific policy; social opinion and thought; and pedagogy, psychology, and human development.

Obviously, such a broad arena exceeds the range of an encyclopedia entry. More importantly, however, we may ask if this very generality of the concept is either informative or useful? With these caveats in mind, this entry takes a more simple, and more materialist, critical, approach.

Instead of focusing on the “information explosion” as a fact, particularly in the general manner in which the term is often couched, we will ask if this term makes any sense and how it does so. Though the concept of the “information explosion” is often taken as representing an empirical fact, in this entry we will suggest that, as a general historical and social concept, at least, it functions as a rhetorical device in “information society” literatures. The term may seem to refer to an empirical fact, but as we will suggest, the term, in its often used generality, is difficult to define and to empirically validate, it is emphatic and emotive (“explosion”), and it is often embedded in arguments that are rhetorically interesting, but empirically specious. The prevalence of the term, particularly in popular accounts of the information age or information society, together with its ambiguity and problematic empirical reference, suggests that the proper approach to this topic is that of critical informatics, as a subset of social informatics, and in particular, as an analysis of the term’s rhetorical forms and discursive contexts. From this perspective, the term’s meaning may be better understood by its rhetorical deployments in social space and as cultural forms of expression, rather than by countless—and always limited—enumerations of its supposed empirical referents.

The initial task facing a critical understanding of the term “information explosion” is to ask, just what is it that is “information” which is supposed to have “exploded,” and if there is a relative overproduction or “overload” of information, then why do we use the rather dramatic term of “explosion” and what are the consequences of the use of such language?

Some of the problems involved with arguing for an information explosion can be gleaned in Peter Lyman and Hal R. Varian’s report, “How Much Information? 2003.”^[1] Lyman and Varian’s report covers the growth (and occasional decrease) in information production across the globe across a wide variety of mediums as measured in bytes of information.

Our interest in pointing to Lyman and Varian’s report is not that of reproducing their findings, findings that are reported yearly in more scattered form in a variety of

governmental and professional yearbooks. Our interest, rather, is to point out a common method of argument in discourses on the “information explosion.” The concept of the information explosion is commonly constructed through an argument that begins with asking something of the order of “how much information is produced (consumed, stored, etc.) in a given period of time or in a given geographical or organizational locale?” Such a question is not only difficult to answer because of the problem of finding standardized data pertaining to the different “forms” of information, but moreover, it is possibly unanswerable in its totality because there is not a common understanding of what the word “information” means. (Capurro and Bjørland have discussed the many different senses of the word “information.”^[2]) For example, by asking “how much information is produced?” are we to include verbal information produced in our ordinary affairs? Are we to include “grey” or informal literature? Are we to include (as Warren Weaver suggested in his commentary on Shannon’s *The Mathematical Theory of Communication*) the “affects” of the performing arts (such as dance—and what would this mean)?^[3] And, if we limit ourselves to presenting evidence about the information explosion to data on the growth of documents, then we are still faced with the problem of what is considered to be a document.^[4,5] And, substituting the term “data” for “documents” and presenting all information measured in terms of bytes blurs the values of different informational forms still further.

Such problems of definition are not marginal to the problem of the information explosion, but rather, their being considered marginal and their being forgotten are at the heart of the term’s success in seemingly representing an empirical event. This forgetting is central to its success in discourses arguing for the social need for professional information management techniques and technologies and information management organizations.

For example, if one had consulted in 2007 the homepage of the contemporary “ischools” consortium (<http://www.ischools.org>), made up of many of the top university schools in information science in the United States, one would have found there an “ExaByte-Counter,” which suggested the need for such schools:

ExaByte-Counter—the number of bytes our world is creating. (One exabyte = 10^{18} bytes)

In 2006, the world created 161 exabytes of new information.

161 exabytes would fill 2 billion 80 GB iPods.

142,000,000,000,000,000 bytes^[6]

The reason why the exabyte data is shown on the web page is, as is often the case in this type of discourse, to persuasively suggest the need for new technical, technological, or in this case, organizational and educational tools and bodies in order to “harness” the “power” of information: “The

iField addresses this fundamental issue: how do we harness that incredible flow of information for the betterment of society, rather than get swamped by it?”^[7]

This statement contains the tropes of “information flow” and, implicitly, “information power” in an unspoken metaphor that equates the ischools with something akin to a hydroelectric plant. Subsequent statements on the ischools’ Web site surrounding the above quote stressed that what we refer to as the information explosion is a product of the Information Age and that it creates conditions of information overload. The rhetorical relation of “the information explosion” to “the Information Age” (or, its near synonym, “the Information Society”) and to “information overload” will be addressed in the following sections of this entry.

It needs to be mentioned first, however, that there are plentiful historical precedents for this type of discourse. Suzanne Briet, “Madame Documentation,” used the same rhetorical strategies as those above to argue for the historical inevitability of the profession of Documentation in the beginning of her 1951 book, *Qu’est-ce que la documentation? (What is Documentation?)*.^[8,9] The father of European Documentation, Paul Otlet, in his writings used the trope of the information explosion as a reason to embark upon his own projects, which included not just written works, but the creation of a world documentation organization and dreams of adding to this a world museum and a world bank. One contemporary author, Alex Wright, has even suggested that the information explosion reaches back to prehistoric times—a rather spectacular claim!^[10] Tefko Saracevic has summarized the view that information science and the development of information technology has been a consequence of the information explosion and the “evolution” of the information society:

Addressing the problem of information explosion, information science found a niche within the broader context of the evolution of the information society. In its various manifestations and attempted solutions, the niche is getting broader and bigger.^[11]

If read deeply, the existence of such discourses suggests that we need to examine not only the rhetorical bases for the deployment of “information explosion” discourses, but we also must examine the larger social forces investing in what are supposedly explained by such discourses and their tropes: namely information infrastructures. This broader task has been undertaken, for example in Geoffrey Bowker’s book, *Memory Practices in the Sciences*.^[12]

INFORMATION SOCIETY

Frank Webster^[13] has well summarized some of the more salient points of a critical analysis of the concept of the “information society.” His comments bear repeating and

bear further commentary in the context of the concept of the “information explosion,” for both terms connote historically unique moments of information mass and overproduction.

One of the most important points that Webster makes in his article is that arguments for asserting the existence of an information society—like arguments asserting the existence of an information explosion—often take the form of asserting a qualitative social change out of the evidence of rhetorically or stylistically impressive data on information production, use, etc. The issue here is that though the data may be rhetorically or stylistically impressive (as in the ischool consortium’s “ExaByte counter”), often there is a lack of a standard for discussing why and how such data is to be used as the basis for making assertions about qualitative historical events or social values. Information society literature, for example, often argues for the existence of an information society based on data that show increases in the production and use of information and of information and communication technologies, the use of such technologies in manufacturing and in other traditionally blue-collar jobs, increases in white-collar education requirements, and various other statistical measures. This argument and these types of data are familiar in the writings of the most well-known presenters of “information society” literature: Daniel Bell, Robert Reich, Manuel Castells, etc. These arguments also sometimes appear in Knowledge Management literature as quantitative evidence for arguments asserting the reality of post-Fordism and other “post-industrial” events and values, leading up to the appearance and supposed social importance of Knowledge Management. As Webster argues, however,

...quantitative measures—simply more information—cannot of themselves identify a break with previous systems, while it is at least theoretically possible to regard small but decisive quantitative changes as marking a system break. . . . What we have here is the assumption that quantitative increases transform—in unspecified ways—into qualitative changes in the social system.^[14]

The assumption that quantitative data can give evidence of an historical event or social value without also supplying criteria for the translation of the quantitative data to the qualitative values invites a mischievous use of numbers and statistics for purely persuasive, rather than reasoned, purposes. As we have suggested, this is but one reason for suspecting that information explosion discourse, particularly in the generalist and historicist literature in which it is often found, is more polemical than empirically sound. Another suspicion is aroused by the use of the common standard of bytes for measuring informational units whose meaning and social value cannot be measured by such. (For example, stating that a book is made up of x number of electronic bytes [assuming that it

is in an electronic format] tells us nothing about its informational value in the manner that we usually say that books give their readers information.) No massive number of bytes and no well-known professional authorities can hide the fact that such arguments are specious. Data showing increases in library holdings, publication rates, and data production alone tells us nothing about the qualitative social importance of such numbers unless real historical and social effects are explained and demonstrated. And the ability to demonstrate an “information explosion” across seemingly endless varieties of documentary forms and communication events is very problematic, not only for reasons of reliable statistics, but for the more fundamental reason that the term “information” is a figure of speech that covers many different documentary forms and communication events without a reliable common element which could be pointed to for comparison between, or for combining, these forms and events.

INFORMATION OVERLOAD

If we are to account for the rhetoric of the “information explosion” we may do so in terms of its argumentative forms for evidence (quantitative data, citations to well-known authors, etc.) and in terms of its association to other claimed qualitative events and values (such as “the information society”). If the information society is often discussed as the outward manifestation of an information explosion (or just as often, the information explosion as an outward manifestation of an information society), the “inward” or psychological effect of an information explosion is often argued in terms of “information overload.” “Information overload” is often discussed in the literature in terms of a person being “overloaded” either by a single event of too much information or by the effect of an “information explosion” on a social scale.

Mary Jo Rudd and Joel Rudd in an article on the impact of the information explosion on library users distinguish information explosion and information “load” and “overload” in terms of causes and their effects.^[15] They suggest that the results of early experiments into information overload should be approached cautiously since such results fail to adequately account for personal selections of information “input” and personal avoidance behaviors for preventing “overload.” Further, however, we might add that the information processing metaphors used in Rudd and Rudd’s article are especially peculiar, for library patrons are traditionally thought of in terms of seeking information for particular needs, not as information processing systems. Given a needs-based agent it is hard to imagine an overloaded mental apparatus since needs give way to more needs or no needs when the patron is “satisfied” or ready to move on or simply stops or quits his or her search. The point is that the “information overload” trope may not work very well as even traditional explanations

explanatory devices in an of information seeking. The “information overload” trope seems to be a personal psychological equivalent to the social “information explosion” trope: both work on an energy flow metaphor for information (as we saw with the ischools consortium Web site). Indeed, these two tropes sometimes cross in the literature so that information overloads are said to occur both in terms of personal psychology and in terms of social systems.

Of course, there are many writers who suggest various psychological conditions resulting from information overload in the sense of what is sometimes called, “media overload.” The theme of information or stimulus overload goes back to the beginnings of industrial modernity, while complaints of media overload, specifically, are a bit more recent, tending to become louder in the 1930s, but continuing on through today, now focusing on digital information.

One of the more fascinating commentators on information overload may be the Italian social commentator, Franco Berardi (also known as “Bifo”). What make Berardi’s commentary so fascinating are his claims that information overload largely accounts for the rise of certain psychopathologies, such as panic disorder and depression. In many of his writings of the past 15 years, not the least being his book *La fabbrica dell’infelicità* (*The Factory of Unhappiness*),^[16] the advent of panic as a psychological disorder (panic disorder became a psychological disorder of its own—derived from the Freudian category of anxiety neurosis—only with the publication of the third edition of the *Diagnostic and Statistical Manual of Mental Disorders* [DSM III] in 1980) is linked to information overload, and the subsequent depression which occurs when the person finds him or herself unable to position his or her potential actions in this overload of stimulation. Interestingly, we may recall that Immanuel Kant, too, described a similar psychological phenomenon in his *Critique of Judgment*; the “natural sublime” or the “infinite sublime” are experienced as moments of expansive awe, and even fear and trepidation, leading to a loss of possibilities for personal action, and thus perhaps, we may speculate, eventually resulting in depression. Being in a pre-electric age, of course, Kant did not have access to the electric energy metaphor. Berardi’s is a modern account of the origins of psychological diseases (particularly, panic disorder) as caused by information overload, particularly in the form of media overload.

Another account of the effect of information overload is reviewed in Frank Webster’s previously mentioned article. This is what is sometimes referred to as a “postmodern” reading of information overload where the referential quality of language is understood as breaking down in the midst of a proliferation of signs. Particularly in the contemporary political sphere, language is sometimes critically viewed as being self-referential, its meaning

reinforced by repetition and networks of supporting signification which have no real referent, so that it might be said that “the real” disappears beneath a “simulacrum” of signs. Viewed on the vast plains of culture and society, however, the truth of this claim is difficult to judge. The complaint, really, is much the same as that of Plato and others against the sophists and rhetoricians in antiquity. What we could add in order to make a theory built around such a claim more useful is the suggestion that what is psychologically lost in the midst of multiple representations of reality are the various manners by which evidence is ascertained and by which claims about reality are justified and proven. The basis for the charge of relativism is often a feeling that criteria for judgment have been left out. The problem may not be with either an accumulation or heterogeneity of stimuli or information resources, but with a demand that all types of information be treated in the same manner. Such a demand can become more pressing or “overloading” when many information types are presented to a viewer or reader simultaneously. Conversely, the problem can also be due to a generalized semiotic grammar that is used to represent all matters in the same general form (such as in the mass media) or it can be caused by the view that many different types of semiotic inscriptions constitute equally necessary and valid “forms” of information that equally need our immediate attention. In some of the literature of this type (e.g., that of Guy Debord, Jean Baudrillard, etc.) it seems that it is not an “overload” of signs, per se, that is the issue, but rather, the problems are those of semiotic similarity and a politically motivated aesthetic leveling or foreclosure of possibilities for analysis and judgment, which these authors then point to as the source for the modern “spectacle” or simulacra. Here, the concept of “overload,” in the sense of an “information explosion,” can refer to a variety of phenomena rooted in media production, rhetoric, aesthetics, culture, and politics.

CONCLUSION

In this entry we have suggested that the term “information explosion” needs to be treated as a rhetorical device. We are led to this approach by the rhetorical roles that the term serves in arguments suggesting the historical and social necessity of new information technologies and infrastructures and by its association to other tropes such as “the information age,” “the information society,” and “information overload.” What such an analysis does is to force one to explain what are the specific values of information tools, agents, organizations, and other information infrastructures and cyberinfrastructures and what are their specific social and historical origins and possibilities, once we have eliminated explanations based on the reified trope of the “information explosion.”

Information Management

Brian Detlor

Information Systems, McMaster University, Hamilton, Ontario, Canada

Abstract

Information management concerns the control over how information is created, acquired, organized, stored, distributed, and used as a means of promoting efficient and effective information access, processing, and use by people and organizations. Historically, three perspectives of information management have dominated the Library and Information Science literature: the organizational, library, and personal perspectives. Each deals with the management of the processes involved in the information life cycle. Each concerns itself with the management of different types of information resources. Today, a more consolidated view of information management in the LIS literature exists, largely due to driving forces in society such as digital convergence, changing library roles, and the emergence and popularity of Big Data. These forces have elevated the significance of information management and have raised awareness among people and organizations today of the importance and need to manage information both effectively and efficiently.

INTRODUCTION

Information management (IM) is a broad conceptual term that has various meanings and interpretations among different constituencies. Frequently the term is used interchangeably with others. For instance, IM is often equated with the management of information resources, the management of information technology (IT), or the management of information policies or standards.^[1] Some suggest that IM draws upon ideas from both librarianship and information science.^[2] The purpose of this entry is to clarify the meaning of the term information management, to showcase its major historical perspectives in the Library and Information Science (LIS) literature, and to illustrate how a more consolidated, holistic perspective exists today.

What is IM? IM is the management of the processes and systems that create, acquire, organize, store, distribute, and use information. The goal of IM is to help people and organizations access, process, and use information efficiently and effectively. Doing so helps organizations operate more competitively and strategically, and helps people better accomplish their tasks and become better informed.

This entry adopts a process orientation toward IM where IM is viewed as the control over the information life cycle. Various models of information processes exist; some of the major processes involved in information life cycle concern those that create, acquire, organize, store, distribute, and use information.

Importantly, this entry recognizes three major historical perspectives of IM found in the LIS literature: the organizational, library, and personal perspectives. By far, the organizational perspective has been the most predominant and popular. In a nutshell, this perspective deals with

the management of all information processes involved in the information life cycle with the goal of helping an organization reach its competitive and strategic objectives. A variety of information resources are managed by organizations. These include transactional information stored in databases, summarized information found in data warehouses, and unstructured information content found in documents and reports. From the organizational perspective, the management of IT is a major component of any IM plan. It is with this perspective where associated terms like information systems management, IT management, data management, business intelligence, competitive intelligence, content management, and records management have relevance.

The library perspective of IM recognizes the unique role of information provision organizations, such as libraries, whose central mandate is to provide clientele with access to information resources and services. As such, these types of organizations historically have viewed IM primarily as the management of information collections, such as books and journals. With respect to this historical view, libraries are neither the creators nor the users of this information. As such, the historical library perspective deals with the management of a subset of information processes involved in the information life cycle with the goal of helping library patrons access and borrow information items held in collections. It is with the library perspective where associated terms like knowledge organization, classification, cataloguing, digital libraries, indexes, and information retrieval systems have relevance.

The personal perspective of IM, though not strong in the LIS literature, is similar to the organizational perspective in that it involves the management of all information processes in the information life cycle. The major

difference, however, is that the organizational perspective concerns the management of information of interest to the success and well-being of an organization, while the personal perspective deals with the management of information of relevance and concern to the individual.

Importantly, a consolidated view of these three major perspectives has recently emerged over the last few years in the LIS literature. This consolidation is a result of several new shaping forces in society. One is digital convergence—the digitizing of traditional media—where a convergence of ITs and information content is happening. Another is changing library roles where libraries themselves are involved in the creation of information. A third force is Big Data where organizations and people are generating data at unprecedented levels and at an incredible pace, and analyzing this data in the hopes of discovering new patterns, associations, and insights.

In terms of this entry's organization, the remainder is structured to further explain the major points just described. First, description is given on the information life cycle and the process view of IM. This is followed by a detailed discussion on each of the three major historical perspectives of IM from an LIS vantage point: the organizational, library, and personal perspectives. Next, discussion ensues on how societal forces are helping to shape a consolidated view of IM in the LIS literature. Last, concluding remarks are made.

A PROCESS VIEW OF IM

Leading IM scholars and organizations purport a process-driven view of IM. For example, Wilson defines IM as “the application of management principles to the acquisition, organization, control, dissemination and use of information relevant to the effective operation of organizations of all kinds.”^[3] Similarly, Choo defines IM as the management of processes that acquire, create, organize, distribute, and use information.^[1] Likewise, the US Government Accountability Office defines IM as “the planning, budgeting, manipulating, and controlling of information throughout its life cycle.”^[4]

The conceptualization of IM from a process perspective emerged in the early 1990s.^[5,6] Advocates of this approach stress that a process model of IM should encompass all or some parts of the information value chain or life cycle. Choo proposes six discrete information-related processes or activities that need to be managed: 1) identification of information needs, 2) acquisition of information to address those needs, 3) organization and storage of information, 4) design and development of information products, 5) distribution of information, and 6) information use.^[1] Wilson positions the creation and use of information outside the IM rubric and purports the following six information-related processes pertain to IM: 1) acquisition, 2) organization, 3) storage, 4) retrieval, 5) access/lending,

and 6) dissemination.^[7] Not all IM frameworks include information needs identification and information use as processes to be managed. However, many see the most critical issue facing information managers is eliciting information requirements and matching those information needs in the design and delivery of information systems to promote effective and efficient information use.^[1,8,9]

With respect to this entry, the following are considered to be the predominant information processes to be managed in IM: information creation, acquisition, organization, storage, distribution, and use. Information creation is the process where individuals and organizations generate and produce new information artifacts and items. Information acquisition is the process where information items are obtained from external sources. Information organization is the process of indexing or classifying information in ways that support easy retrieval at later points in time. Information storage is the process of physically housing information content in structures such as databases or file systems. Information distribution is the process of disseminating, transporting, or sharing information. Information use is the process where individuals and organizations utilize and apply information made available to them. Effectively managing these information processes helps get the right information to the right people in the right forms at the right times and at reasonable costs.^[1,10]

THE ORGANIZATIONAL PERSPECTIVE

The organizational perspective is the most predominant perspective of IM. Under the organizational perspective, IM concerns the management and control over the full life cycle of information processes ranging from creation to use for the betterment of the organization itself. In this sense, the management of information processes is seen as a strategic advantage that affords four kinds of benefits to an organization: 1) a reduction of costs; 2) a reduction of uncertainty or risks; 3) added value to existing products and services; and 4) the creation of new value through the introduction of new information-based products and services.^[11]

Information as a Resource

Fundamental to the organizational perspective of IM is the view and treatment of information as a strategic resource—one that needs to be managed like any other critical organizational resource, such as people, equipment, and capital. Many organizations recognize the potential value of information and the need to be aware of what information resources exist in an organization, and the costs associated with acquiring, storing, processing, and using that information. Forward-looking companies consider information as a strategic asset that can be leveraged into a competitive advantage in the markets served by the company.^[8]

The concept of managing information as an organizational resource emerged in the late 1970s with the creation of the US Paperwork Reduction Act that was established to resolve the huge costs of managing and handling information by bidders for government contracts.^[12] It was at this time that the term information resources management (IRM) became popular and was used to signify the management of both information and ITs.^[13,14] In reality though, the IRM concept was more about the management of data than it was about the management of other types of information, such as documents or reports. Case in point, an empirical assessment of the IRM construct defines IRM as “a comprehensive approach to planning, organizing, budgeting, directing, monitoring and controlling the people, funding, technologies and activities associated with acquiring, storing, processing and distributing *data* to meet a business need for the benefit of the enterprise”—not other types of information (*italics added for emphasis*).^[15]

This entry suggests that within the organizational perspective of IM, IM is more than just the management of data (e.g., raw facts stored in transactional databases). Rather, IM in organizations involves the management of a varied set of information resources, ranging from data to information.^[16]

Data can be considered as “raw facts” that reflect the characteristics of an event or entity. Examples of data items held in an organization would be a customer name, an order quantity, or a unit price. The management of data in organizations traditionally belonged to the “data management” function or “data resource management” department. Data management deals with the storage and processing of low-level data items found in transaction processing systems. The focus of data management is to maximize the speed, accuracy, and efficiency of processing and maintaining transactions or records.^[1] Data management is concerned with the creation and “acquisition of data, its storage in databases, its manipulation or processing to produce new (value-added) data and reports via application programs, and the transmission (communication) of the data or resulting reports.”^[8]

Information can be viewed as “meaningful data” where data have been converted into a meaningful and useful context, such as in the identification of a best-selling or worst-selling product item from historical sales data for a company. Examples of information items managed in a company would be summarized information pulled from transactional database systems and stored in data warehouses and/or data marts. Such “business intelligent” systems support decision-making and allow for the slicing-and-dicing of summarized transactional information to find patterns and trends in operational data (e.g., sales data, supplier data, customer profile data) of importance and relevance to the organization. For example, the mining of summarized transactional data stored in a data warehouse could be used to justify the promotion of a

product or service to an untapped market segment, or to measure the effectiveness of a marketing campaign in a certain geographical area.^[16]

Though more emphasis in organizations is placed on the management of data and information that is structured and formalized (i.e., data neatly contained within a transactional database or summarized information stored in a data warehouse), the amount of unstructured information that is created, acquired, organized, stored, distributed, and used within an organization usually far exceeds the amount of structured data and information an organization manages.

Unstructured information is the type of information that can be found in reports, documents, email messages, and PowerPoint presentations, among others. This includes reports and documentation generated internally with a company and outside the enterprise as well. For example, managing information concerning industry trends, legislative regulations, competitor happenings, news bulletins, etc., is key to helping an organization stay abreast and react to competitor threats and environmental concerns. This is where IM intersects with a company’s “competitive intelligence” initiatives and “environmental scanning” activities. Competitive intelligence refers to the analysis of information about competitors and competitive conditions in particular industries or regions.^[17] Environmental scanning refers to the analysis of information about every sector of the external environment that can help an organization plan for its future.^[18,19]

Often, document management systems, also known as content management systems, help manage unstructured information that is created, acquired, organized, stored, distributed, and used within an organization. These systems support the electronic capture, storage, distribution, archiving, and accessing of documents. These systems typically provide a document repository where documents can be housed, indexed, and accessed. In these repositories, metadata information is maintained about each document that tracks each document’s editorial history and relationships to other documents. Indexing of documents within these systems, through both manual keyword classifications and automatic indexing techniques, facilitates easy document retrieval by organizational workers at later points in time.^[16]

Unstructured information also includes records of transactional information processing such as invoices, contracts, order requisitions, bills of lading, and financial statements. The actual data may be resident in a transaction database and managed elsewhere, but the entire record of the event, often with signatures, are handled as a complete entity that must be generated, stored, processed, retrieved, and archived. The management of such information is referred to as “records management” and involves the application of systematic and scientific control to all recorded information that an organization needs to do business.^[20]

Managing Information Processes

A good IM program in an organization will manage the full life cycle of information ranging from creation to use. For example:

- When generating transactional data, steps will be taken to ensure that the data will be stored following database “normalization rules” to promote data integrity, the single sourcing of data, the reduction of wasted database space, and fast transaction processing.
- When acquiring information, such as the purchase of market research data or competitor intelligence information, steps will be taken to reduce duplicate purchases and to increase the accessibility of any purchased data and information across the enterprise.
- Any data or information that is stored will be adequately protected against unauthorized access, as security, privacy, and copyright concerns exist.
- Data and information stewardship programs will be set up to identify those organizational workers or units who are responsible for the quality and management of certain data and information items.
- Data and information will be regularly backed up for recovery purposes.
- Duplicate or mirror copies of data and information items will be created to facilitate access and reduce network congestion and/or an overload of requests on the servers on which the data and information reside.
- Old data and outdated information will be archived and/or deleted.^[16]

IT's Role

IT plays a critical role in the management of information in organizations. However, having said that, it should be understood that IT is the technical medium upon which information is housed, accessed, retrieved, distributed, and used, and not the primary entity that is being managed under the IM rubric. Information processes are the entities being managed.

Nevertheless, much confusion exists over the role IT plays in the management of information in organizations, with some equating IM primarily to the management of IT itself. For example, the mission of the Society for Information Management, a professional society for chief information officers and senior IT leaders based in the United States, emphasizes the management and use of IT to achieve business objectives.^[21] Likewise, Davis and Hamilton define IM as “the management of information systems and information resources by an individual, a group, or an organization” and describe IM as a “new business function with responsibility to define organizational informational requirements, plan and build an information infrastructure and information systems applications, operate the system, and organize, staff, and manage these activities.”^[22]

This entry suggests that such descriptions of the IM function in organizations are inappropriate and are better served by alternate terms such as information systems management or IT management. Information systems management refers to the control over the development, design, roll-out, and support of information systems applications that support business processes and workflow. IT management refers to the management and control over IT (e.g., hardware, software).

A variety of factors need to be considered when managing technology in organizations. The appropriate hardware and software needs to be installed and implemented. Repair and maintenance of hardware and software systems must be done. Licensing concerns must be taken into consideration. Information systems professionals (e.g., programmers, network specialists, database administrators, systems analysts) need to be hired and trained.^[16]

IT is very important to how information is managed in organizations, and the management of IT should be an integral part of any IM plan.^[11] After all, IT facilitates the ability to support information creation, acquisition, organization, storage, distribution, and use in both efficient and effective manners.

Organizational Information Processing

IM is concerned with organizational information processing. Two broad orientations exist in the organizational information processing literature that have implications on IM.^[23]

The first, mainly developed at Carnegie Mellon University and represented by Herbert Simon, James March, and Richard Cyert, sees an organization's ability to process information as the core of managerial and organizational competencies and organizations as bounded, rational systems.^[24] Here, strategies to improve information processing capabilities concern increasing an organization's information processing capacity and reducing an organization's need for information processing.^[25]

The second, represented by Karl Weick and Richard Daft, sees organizations as loosely coupled systems where individual participants collectively develop shared interpretations of the environment and then act on the basis of this interpretation. In this sense, information processing is about reducing the equivocality or ambiguousness of information about the organization's external environment.^[26]

Taking these two orientations of organizational information processing together, IM then is about increasing an organization's information processing capacity and reducing both information processing needs and information equivocality.

Of interest, how an organization processes information is influenced by its information culture (i.e., the shared assumptions, values, norms, and behaviors that shape an organization's perception, management, and use of information).^[27] Specifically, four types of information cultures

exist (results-oriented, rule-following, relationship-based, and risk-taking) and each has influence on how an organization manages information. In a results-oriented culture, the goal of IM is to enable the organization to compete and succeed in the marketplace. In a rule-following culture, information is managed to control internal operations and to reinforce rules and policies. In a relationship culture, information is managed to encourage communication, participation, and a sense of identity. In a risk-taking culture, information is managed to encourage innovation, creativity, and the exploration of new ideas. Most organizations would display varying degrees of each of these four types of IM norms and behaviors.^[28]

THE LIBRARY PERSPECTIVE

Outside of the organizational context, IM also has meaning in the library world and to other information provision organizations whose central mandate is to provide clientele with access to information resources and services. IM is of concern to all kinds of libraries, such as public libraries and academic and research libraries. This includes corporate libraries that manage serial subscriptions and electronic access to industry reports and electronic databases for workers and employees in their organizations.

From a library perspective, IM concerns the management of information collections, such as books and journals. The goal of IM from a library perspective is to help library patrons access and borrow information items held in the collection. A variety of activities surround the management of a library collection, including the development of collection policies and materials budgets, the selection of collection items, the analysis of collection usage and end user collection needs, training of collection staff, preservation of collection items, and the development of cooperative collections with other institutions.^[29]

Since historically libraries have neither been creators nor users of information, this perspective deals with the management of a subset of information processes involved in the information life cycle. For example, Wilson identifies six information-related processes pertaining to IM that are applicable to the library perspective: 1) acquisition, 2) organization, 3) storage, 4) retrieval, 5) access/lending, and 6) dissemination.^[7]

Information acquisition involves the process of buying or securing information from sources external to the library for the collection. Care must be taken to ensure that the correct information items are acquired (those that match the information needs of end users) and at reasonable costs.

Information organization pertains to the process of indexing or classifying information housed in the collection to support easy retrieval at later points in time. Today, this process is sometimes referred to as “knowledge organization” in the library world. For example, the International

Society for Knowledge Organization utilizes the term “knowledge organization” to represent the process of how documents, document representations (such as bibliographic records), and concepts (keywords, constructs) are ordered and classified.^[30] Likewise, Anderson defines knowledge organization as the “the description of documents, their contents, features and purposes, and the organization of these descriptions so as to make these documents and their parts accessible to persons seeking them or the messages that they contain” and describes how knowledge organization encompasses “every type and method of indexing, abstracting, cataloguing, classification, records management, bibliography and the creation of textual or bibliographic databases for information retrieval.”^[31] In this sense, knowledge organization deals with both processes and systems.^[32] With respect to IM, this entry suggests that the use of the “knowledge organization” label is misleading. In actuality, information items (such as documents and document representations) are being organized or ordered (i.e., indexed, classified, catalogued) rather than knowledge items (concepts, constructs) *per se*. As such, “information organization” is suggested to be a better label to use when talking about the indexing and classification of items held in a collection, at least from a library perspective of IM.

Information storage refers to physically housing items in the collection. This encompasses the housing of both paper and electronic documents (and their document representations). This could be accomplished by storing books and journals in physical stacks in the library or storing full-text electronic versions of documents in an electronic or digital library.

Information retrieval involves the process of searching and finding information in the collection. Typically, end users will conduct a search query using electronic tools that are Web-based to find items of interest in the collection. In the information retrieval process, end users themselves, or information search intermediaries (librarians) working on the behalf of end users, “pull” the information that is needed from the collection.

Information access/lending involves the process of providing physical or electronic access to the collection and the ability to check out information items of interest. For paper-based documents, this may involve signing out and borrowing a physical information item. For information in electronic form, this may involve viewing the information item online and/or downloading a copy of the information item from the collection.

Information dissemination is the process of circulating physical information items of interest from the collection to end users. Traditionally, methods of dissemination involve the distribution of photocopied journal content pages or the circulation of documents. Today, this has largely been replaced with electronic alert services that “push” information items in the collection of interest to specific users based on stored end user profiles.

The management of library information collections is a complex and ever-evolving process.^[33] The extensive digitization of information resources has placed new pressures on libraries to respond to securing the requisite skills, resources, and competencies to successfully manage digital library collections.^[34] In order to manage the transition and reliance on digital information collections, it is important more than ever for libraries to consider the expectations and needs of end users, as well as limitations in library staff and budget adaptability.^[33] These are critical factors in rolling out any successful IM program from a library perspective.

THE PERSONAL PERSPECTIVE

IM from the personal perspective refers to how individuals create, acquire, organize, store, distribute, and use information for personal purposes.^[35,36] This can concern the management of information for everyday use (e.g., personal calendars, schedules, diaries, news items) or work-related reasons (e.g., work schedules, things-to-do, project files). As such, personal IM involves the handling and processing of information over the entire information life cycle, just as in the case of the organizational perspective. However, the personal IM perspective differs from the organizational perspective of IM in that personal IM concerns items of interest to the individual, not the organization.

Central to the personal perspective of IM is the need to manage the information processes of information creation, acquisition, organization, distribution, and use so that the right information is accessible and available in the right place, in the right form, and of sufficient completeness and quality to meet personal information needs. A variety of information items are created, acquired, organized, stored, distributed, and used by people for personal purposes. These include personal notes, personal journals, web pages, email messages, news articles, address books, calendar dates, reminders, fax communications, etc.

Technologies and tools, such as electronic personal information managers like PDAs, help people carry out these processes more efficiently and effectively.^[37,38] Cheap and fast search and storage technologies bring stability and order to people's often chaotic and messy personal information environments, and facilitate making the most of people's personal information collections.^[39] Despite the benefits of these technological tools, there is some evidence to suggest that technological advances are less important in determining how individuals organize and use information than are the tasks that people perform,^[40] and that improvements in personal ITs are required, specifically in terms of minimizing information overload, supporting easier context switching, and providing better integration across a variety of applications.^[41]

It is interesting to note that the phrase "personal information management" was first used in the 1980s with the

advent of personal computers and their capacity to process and manage information.^[42] However, the concept of "personal information management" was most likely first implied back in 1945 by Vannevar Bush when he envisioned using the "Memex" machine for personal IM—a machine that allowed an individual to store all his or her books, records, and communications and consult those personal information sources with great speed and flexibility.^[43]

As the proliferation of personal computing devices and the explosion of the amount of information that is created, generated, and used continues to increase, the relevance of IM from the personal perspective will likely gain more attention and importance from both researchers and practitioners alike.

TOWARD A CONSOLIDATED VIEW

Though, historically, the three major perspectives of IM described earlier (i.e., the organizational, library, and personal perspectives) were formed independently from each other, a variety of recent societal forces have led to the formation of a new consolidated view. These forces include digital convergence, changing library roles, and the emergence of Big Data.

Digital convergence involves the coming together of previously distinct products and services that employ digital technologies.^[44] According to a report by Deloitte, digital convergence is driven by three underlying trends: 1) the proliferation of digital data, which provides a common base for handling diverse types of information using the same devices, processing techniques, and media; 2) widespread connectivity, which helps bring diverse information together, and extends the value and capabilities of a device beyond its out-of-the-box functionality; and 3) continuous advances in technology, from battery life to processor speed.^[45] As digital convergence has occurred, organizations, libraries, and individuals have become accustomed to working with information systems that are not strictly contained to a specific organizational, library, or personal content domain, or restricted to a specific type of IT. Rather, organizations, libraries, and people are now more accustomed to working with digital technologies and devices that allow the gathering, collection, access, and use of information from a wide variety of sources and to using the same type of ITs to do so. As such, organizations, libraries, and people have been accustomed to utilizing the same types of ITs to access, collect, store, and use information.

Libraries have embraced content creation. This is a new and expanded role for libraries. Today, one can easily find libraries involved in the creation of new information through the provision of maker-spaces,^[46,47] open-access online journals,^[48,49] institutional repositories,^[50,51] and the generation of digital storytelling collections.^[52,53]

Further, academic libraries now play a lead role in the stewardship of institutional research data.^[54,55] This new recent content-creation role has increased the breadth of information processes in the information life cycle for libraries and made libraries more closely aligned with the information processes one would find in the organizational and personal IM perspectives.

Big Data refers to the tools, processes, and procedures that allow an organization to create, manipulate, and manage very large data sets and storage facilities.^[56] One of the primary reasons for Big Data is “data explosion,” largely due to the widespread accessibility, affordability, and availability of new digital devices, such as smartphones, tablets, and laptops, that make access to the Internet both easy and relatively inexpensive for billions of people worldwide. Another is that the list of data sources keeps growing as organizations and consumers generate different and vast amounts of data every day by emailing, searching, browsing, blogging, tweeting, and texting.^[57] Organizations are scrambling to leverage the overwhelming amount of Web-based, mobile, and sensor-generated data arriving at terabyte and even exabyte levels afforded by Big Data by analyzing this highly detailed, contextualized and rich content in the hopes of making insights and new discoveries for competitive and business success.^[58] The proliferation of Big Data enables companies to harness the power of predictive analysis.^[59] Of importance to this entry, organizations that wish to leverage Big Data recognize the need to follow sound IM principles.^[60] In this regard, Big Data has raised awareness of the critical importance of IM and the need to manage information efficiently and effectively more than ever before.

CONCLUSION

This entry provided a review and discussion of the IM concept. Importantly, a process-oriented definition of IM was proposed and three distinct historical perspectives of IM from an LIS vantage point were described: the organizational, library, and personal perspectives. Importantly, a consolidated view of these three historical perspectives was suggested based on recent trends and happenings.

This entry emphasized the importance of IM. IM allows organizations to reach strategic goals and make sound decisions. IM enables libraries and other information provision organizations to manage information collections effectively and efficiently. IM helps people manage their own personal information collections.

This entry also described how IM is not so much about the management of technology, but rather more about the management of the processes of IM, specifically the creation, acquisition, organization, storage, distribution, and usage of information.

According to the current scope of the *International Journal of Information Management*, the challenge for IM now is less about managing activities that collect, store, and

disseminate information, and more about placing greater focus on managing activities that make changes in patterns of behavior of customers, people, and organizations, and information that leads to changes in the way people use information.^[61] This may not be such an easy task. People and their information behaviors are hard to change. So are organizational cultures.^[11] IM is less about solving technical problems and more about addressing the human-side of IM. Humans add the context, meaning, and value to information, and it is humans who benefit and use this information. As such, “mastering information management is an essentially human task.”^[62]

Information Needs

Charles M. Naumer

Karen E. Fisher

Information School, University of Washington, Seattle, Washington, U.S.A.

Abstract

The following entry describes the concept of “information need.” The concept of “information need” has no single definition but is dependent on the perspective from which it is applied. The concept of “information need” is discussed in terms of its definition in other fields, involvement with the user-centered paradigm, and articulation in key models of information seeking, as well as how it has spurred new avenues of inquiry within library and information science (LIS).

INTRODUCTION

“Information need” is one of the most central concepts within library and information science (LIS). If people did not have information needs, then libraries and other information systems would cease to exist, even basic interpersonal human communication would be altered. An in-depth understanding of “information needs” is critical to answering some of the larger questions facing LIS from an individual, organizational, and societal perspective. These questions include: (1) how are information needs created? (2) what motivates people to seek information? (3) why do people sometimes avoid information? (4) how do people express information needs? (5) how is relevance considered? (6) how should information be organized and managed to best respond and anticipate people’s needs? and (7) how should we organize and plan for the expression of information need? LIS professionals thus require an understanding of what an information need comprises, how it develops, is met, and transforms in order to provide optimal service in collection development, cataloging, and reference—to name a few key library functions. System designers and professionals in other fields require in-depth understanding to meet users’ needs through their services as well. However, while libraries have existed for millennia, formal understanding of information needs from a user perspective has only been explored since the 1960s.

SITUATING INFORMATION NEEDS

In order to understand the term “information needs” it is important to understand how it is situated within the general context of “human needs” research as well as within the evolutionary trajectory of LIS. “Needs” or “human needs” is a central concept in many disciplines. In order to fully consider the meaning of the term information

needs, it will be examined within the general context of “human needs” research. A multidisciplinary examination of the importance of “needs” research provides an essential context for understanding the concept of “information needs” within LIS and especially from a user-centered perspective. The use of this term will also be explored as part of the historical development of the LIS field and its role in spurring new avenues of inquiry within the field.

The Definition of “Need” in Cognate Fields

The concept of “need” is unsurprisingly central to many different disciplines. Perhaps the best known is psychology and Maslow’s hierarchy of needs.^[1] Maslow’s theory of human motivation contends that human needs can be organized into a hierarchy or a pyramid of five types of needs. At the bottom of the pyramid are basic or physiological needs such as breathing, food, water, sex, and sleep. The next level relates to safety including physical security, employment, property, and resources. Above this level is a sense of love and belonging associated with friendship, family, and intimacy. At the next level is esteem which is reflected in self-esteem, confidence, and respect by others. Lastly, Maslow described the highest level of need being self-actualization, which is characterized as involving personal development associated with morality, creativity, spontaneity, and problem solving. Maslow’s hierarchy is often used as the basis for understanding human motivation. Another, simpler, categorization of human need by psychologists is that of: (1) physiological need; (2) affective need; and (3) cognitive need.^[2]

Human needs are also of central concern in the field of economics and political science. Human need is considered a driving force in the demand for goods and services. Human needs theory has played a prominent role in political economy research as a means of supporting economic development theory. For example, the political economist

and Nobel prize winning scholar Amartya Sen based his arguments on the moral grounds for public spending on a definition of human needs.^[3] Political scientists have also used theories of human needs as a way to better understand conditions for peace, conflict resolution, and negotiation.^[4]

Perhaps most closely related to many of the inquiries on information need in LIS is the definition of “educational need.” The concept of need in the field of education has been used both to assess and express individual needs as well as to measure aggregate needs at the local, state, or federal level.^[5–7] Other disciplines, such as health sciences, have conducted their own studies on “information needs” in the context of their fields.^[8]

Information Needs and LIS

Despite its centrality to information seeking, use and sharing the concept of “information need” remains ambiguous in the literature. This difficulty may stem from the fact that it is challenging to create a boundary around the concept of “information needs.” Wilson suggested that an “information need” is secondary to a primary need such as food, shelter, and clothing.^[9] In order to understand an information need, it is often necessary to understand the context of human needs that created a need for information. This approach to understanding information need requires a broad understanding of people’s personal situations. Wilson^[2] also noted that one of the difficulties faced in defining “information needs” is separating the concept from “wants,” “expressed demand,” “satisfied demand,” and so on. He partially attributed this to the “failure to identify the context within which information needs investigations are carried out” (p. 8).^[2] Hjørland^[10] later argued that “it is essential not to confuse the concept of need with the concept of demand.”^[10] To illustrate the difference, Hjørland presented a situation in which the demand for information from a library was low due to factors such as accessibility; yet, the information needs of the people in the community were high.^[10] In this situation, need and demand were clearly not equal.

Green^[11] also considered the differences between “wants,” “demands,” and “needs.”^[11] He identified four aspects as most central to an understanding of the concept of information need: (1) need is necessarily instrumental; (2) needs are usually contestable; (3) need has a strong relationship with necessity; and (4) there is no necessary psychological element in a need. Green also stressed that need does not necessarily mean that information is lacking—a person may need information that they already have.

An explicit information need is often considered to be the motivating force behind a user’s action to seek information. Understanding the motivational factors involved in human information behavior is critical to understanding other parts of the information seeking and use processes

and has raised several important questions. For example, motivation is central to research regarding passive and active approaches to information seeking as well as blunting and avoidance behaviors.

The difficulty of ascertaining a person’s information need has also been cited as cause for lack of a more thorough consideration of the concept. In the early 1980s, Belkin and Vickery^[12] argued that since information needs exist in someone’s head they are very difficult to assess.^[12] Harter^[13] later suggested that information needs are akin to a person’s mental state, arguing that they are in a constant state of flux as a person continually acquires new information.^[13] Given these considerations and the close relationship between information need and other subdisciplines’ consideration of need, it has been suggested that “needs” research may fall outside the scope of LIS and be better suited to other disciplines. Wilson^[2] suggests “it may be advisable to remove the term “information needs” from our professional vocabulary and to speak instead of “information seeking towards the satisfaction of needs” (p. 9).^[2]

Historical Evolution of Information Need Research within LIS

In a historical context, studies concerning “information need” have evolved greatly. In the famous monograph “The Library’s Public,” Berelson^[14] synthesized the results of library studies from 1930 to 1949, and reported that libraries were used primarily for accessing books and were patronized by the younger, better-schooled, culturally alert members of the community.^[14] Despite collecting demographic data, little attention was paid to the types of uses that people made of libraries, especially in connection to particular needs. Most of the studies summarized by Berelson were concerned with “demands” rather than “needs,” and were aimed at informing collection development and circulation practices.

The 1940s and mid-1950s were marked by the vast increase in the amount of scientific literature generated and released in the postwar era. Responding to Vannevar Bush’s call to “make more accessible a bewildering store of knowledge,” researchers began studying how information is used in relation to work focusing particular attention on science and technology.^[15] This type of research was primarily focused on determining how information sources could be made more useful to scientists, and in this context the information needs of scientists were studied.

The 1960s and 1970s ushered in an era in which LIS research focused on social and community issues. Several major, large-scale studies were conducted, including the study of the information needs of urban residents of Baltimore and the “The Humphry Report” of Maine.^[16,17] These public library-oriented studies sought to identify the information needs of large populations. The federal

government through the U.S. Department of Education also demonstrated a strong interest to identify the information needs of citizens. As part of this effort, the U.S. Department of Education funded a study by Ching-chih Chen and Peter Hernon investigating the information seeking patterns of the general public as well as a study by Brenda Dervin examining the information needs of urban residents of Seattle.^[18,19]

A similar large publicly funded study was conducted in Britain during this period. The INISS Project directed by Tom Wilson and David Streatfield studied the communication and information flows in local authority social services departments.^[2] The project was particularly innovative for its use of action research to foster change in the organizations, and employment of qualitative methods such as structured observation. Wilson credited this 5 year project as being a major influence of the ideas expressed in his seminal 1981 paper on user studies and information needs.

During the 1960s and 1970s a new conceptualization of information need also began to emerge. In 1962, Robert Taylor published an article in which he examined the process of information need development as revealed through question asking and answering dialogue at the reference desk of a library.^[20] He followed this article up 4 years later in 1968, with his seminal article "Question-Negotiation and Information Seeking in Libraries."^[21] During this period, other researchers, such as Brenda Dervin were beginning to focus their attention on better understanding the process by which information needs are determined and expressed. The work of these researchers launched a new way of viewing information users and information needs.^[22] In their landmark 1977 work "Public Library Use, Users, Uses" Zweizig and Dervin challenged researchers with identifying the uses (and *possible* uses) that people make of public libraries by focusing on situational needs.^[23] They observed that the time for studying "how much use is made of libraries and by whom" is past, and that focus should be switched from "the user in the life of the library" to "the library in the life of the user."^[23]

In their seminal 1986 ARIST chapter, Dervin and Nilan expounded on the paradigm shift that they claimed had occurred within LIS, a switch in focus from the system-oriented paradigm of past decades to a new user-centered or alternative approach that emphasized constructive, active users, subjective information, situationality, holistic views of experience, internal cognition, and systematic individuality.^[24] At the heart of this paradigm shift was its view of users and their inherent information needs, which were no longer seen as "empty buckets" that could be filled with "bricks of information" (to use Dervin's terminology). Dervin and Nilan gave three examples of such user-centered scholarship: Taylor's user-values or value-added approach, Dervin's Sense-Making approach, and Belkin and colleagues' anomalous states-of-

knowledge approach.^[24] Notable definitions of information need cited by Dervin and Nilan include "a conceptual incongruity in which the person's cognitive structure is not adequate to a task,"^[24,25] "when a person recognizes something wrong in his or her state of knowledge & wishes to resolve the anomaly,"^[26] "when the current state of possessed knowledge is less than needed,"^[27] and "when internal sense runs out" (Dervin, 1980). During this period, Dervin and Dewdney proposed neutral questioning, based on Dervin's Sense-Making approach, as a technique for understanding users' information needs at the reference desk.^[24] Although the paradigm shift is most often associated with the 1980s, Bates contended that the shift actually began occurring in 1960 at the time Moore's Law was published and as represented by Edwin Parker's 1966 argument that "the system should adapt to the receiver or user, rather than the user to the system" (as cited by Bates).^[28] In 1976 Dervin, herself, called for a shift in attention toward designing systems that adapt to users' needs which support their efforts to help themselves to make sense out of information.

Case,^[29] views Dervin's work and specifically the Sense-Making approach to be "the most ambitious attempt to explain the origins of information needs" (p. 75).^[29] Dervin's Sense-Making approach considers "information need" as being derived from a person's desire to make sense out of a situation.^[30] The Sense-Making approach describes a person reaching a point at which they need help to bridge a gap in their understanding. According to the Sense-Making approach, the "gap" represents a crucial point at which a person develops a need for information to allow them to move forward. The "gap" is the point at which a person begins to recognize and articulate their information needs. An important aspect of sense-making as it relates to information need is the recognition that information needs are not isolated but are connected to a larger context. When an information need is considered in a larger context it will be linked to numerous information needs. As one information need is addressed, other needs will likely develop.

The user-centered work of Dervin, Wilson, Kuhlthau, Belkin, and others in the 1970s and 1980s introduced holistic approaches to understanding information behavior and laid the foundation for an exploration of the role of "context" in understanding human information behavior. The 1990s to the present marks a period in which "context" became more deeply considered in all aspects of information behavior. Indeed, in 1996, information seeking in context began developing its own subspecialty within the field of LIS. As research interest coalesced around this topic, a conference was organized in Tampere, Finland and aptly named the Information Seeking in Context (ISIC) conference. According to Pettigrew et al. (2001), "another quantum leap ha[d] occurred within information behavior ... emphasiz[ing] the contextual interplay of cognitive, social, cultural, organizational,

affective, and linguistic factors” [Pettigrew, 2001 #463, p. 67]. Kuhlthau described information seeking in context as “focus[ing] on a holistic view of information needs in the course of people’s lives” (p. 723).^[39]

Social context has been a particularly important aspect of studies of information seeking in context. Chatman’s work exemplifies studies that carefully consider the influences of social contexts on all aspects of information behavior. For example, Chatman’s study of the information behavior of women prisoners suggests that “life in the round will, for everyday purposes, have a negative effect on information seeking” and that “people will not search for information if there is no need to do so. If members of a social world choose to ignore information, it is because their world is working without it” (p. 214).^[32] In this study, Chatman demonstrated a strong connection between information need and the social context or social world of the participants.

Lastly, research on everyday life information seeking (ELIS) has also evolved during this time period [^[34] #1276; ^[35] #1265; ^[36] #1275; ^[37] #1203; ^[38] #433; ^[39] #282]. This research focused on information seeking behavior as part of people’s everyday life experience as compared to job-related information behavior studies.

INFORMATION PARADIGMS AND MODELS

The concept of “information need” can be understood in greater depth according to three theoretical perspectives. As argued by Tuominen, Talja, and Savolainen, information science has evolved in three stages where each stage was dominated by a particular theoretical perspective.^[33] These three perspectives were labeled the “information transfer” model, the “constructivist” model, and the “constructionist” model. These three perspectives might also be termed the physical view, cognitive view, and social view, and are discussed in depth below.

Information Transfer Model

The transfer model or physical view of information need is based on the concept of demand for physical objects. This perspective considers an information system as a process for transmitting “information objects” such as books and documents. Based on this conceptualization, information need might be represented as a request for a physical document. The system might then be measured according to its capacity to deliver the physical objects meeting the information need. This view is tied to the conceptualization of information as a thing. This perspective has been influential in the development of methods to evaluate libraries and other information systems according to their ability to deliver books and documents on demand.

Constructivist or Cognitive View

Under the Constructivist or Cognitive View, “information needs” are seen in terms of the knowledge structures of people. This view seeks to understand information needs based on the mental models, processes, and relationships. Therefore, people’s information needs are based on knowledge or lack of knowledge about a topic, their level of proficiency regarding a process, and the cognitive processes they engage in to make sense of information.

Taylor’s work is exemplary of this constructionist or cognitive view. Considered a pioneer in LIS, before becoming Dean of the School of Information Studies at Syracuse University, Taylor worked as a reference librarian and developed a model of the information seeking process which articulated information need development through question formulation. This concept was described in two articles published in 1962 and 1968, the latter of which is most often cited.^[20,21]

Taylor’s conception of information need advances the idea that people progress through four levels of question formulation:

- Q1—the actual, but unexpressed need for information (the visceral need).
- Q2—the conscious, within brain description of the need (the conscious need).
- Q3—the formal statement of the need (the formalized need).
- Q4—the question as presented to the information system (the compromised need).

Taylor’s model is especially important as it was the first time the suggestion was made that a person may experience a sense of need for information before being conscious of it or able to articulate it. The very notion of such a concept creates an awareness of why professionals should support a user in articulating his or her information need and necessitates shifting the focus from information to that of understanding the user. Taylor’s model recognizes that the information need presented to a system or person is a compromised need and that a negotiation occurs between the stages of recognizing a need and presenting it to an information system. Therefore, the information need expressed to a system in the form of a query, for example, is only a representation of the information need and is constrained by the ability to fully articulate the need through the use of a language or set of tools. Taylor’s work preceded the user-centered shift in information science by close to two decades. Taylor’s levels of information need development continues to be often cited and an important underlying work for much research including the development of subsequent information models such as Belkin’s ASK model, Kuhlthau’s ISP model, and Dervin’s Sense-Making approach.

Informed by Taylor's conception of information need, several theories of information seeking arose that defined "information need" as being motivated by a sense of uncertainty. Theories falling under this category could be considered Belkin's Anomalous State of Knowledge, Kulthau's ISP, and Dervin's Sense-Making methodology.^[24,30,34,35] All these theories explain information need and the motivation for searching for information as being derived from a gap in knowledge which manifests itself as a sense of uncertainty. Although in comparison to Wilson's model they do not explicitly represent an external need that preempts an information need, they all recognize information need as a part of a larger situation. Dervin is especially clear in this regard conceptualizing a user as someone situated in context and in the process of defining their situation. Dervin's approach to situating a user in context has strong implications toward understanding the social view of information behavior although sense-making is most often considered as part of the cognitive view.^[36]

Social Constructionist or Social View

Those espousing a social constructionist perspective (the third theoretical framework according to Tuominen et al.^[33]), criticize the cognitive perspective for failing to fully recognize the impact of the social realm on information behavior. Hjørland, claims that Taylor's information need model is extremely individualistic and argues that "behind the concrete information seeking-process lies an information need that is an integration of the individual and the collective information need" (p. 168).^[10] This perspective and other holistic perspectives recognize that information need is not something static located in the user's head but as something dynamic that changes as the user interacts with information and society as a whole.^[10] This conception of information need recognizes need development as being socially situated, and that the needs of a group may be different than the needs of an individual, the needs of a group should be considered in addition to or instead of the needs of an individual.

Although Wilson's models are most often associated with the cognitive perspective, Wilson's concept of holistic "information need" might also be classified in the social realm. In his second model of 1981, Wilson made two propositions regarding information need. The first proposition argues that information need is a secondary need emerging from a primary need. A primary need is of a more basic nature encompassing needs such as food, shelter, companionship, and employment. Primary needs can be classified as the following:

1. Physiological needs—need for food, water, shelter, etc.
2. Affective needs—need for attainment, domination, etc.
3. Cognitive needs—need to plan, learn, etc.

The second proposition suggests that in the course of seeking information to satisfy their needs individuals will likely run into barriers of different kinds.^[2] In this paper, Wilson also proposed the idea of information behavior in context. The concept of information in context and the development of information needs in context was a precursor to the rise of interest in ISIC.

In his 1996 report Wilson further commented on the lack of progress in assessing information need:

At the root of the problem of information-seeking behaviour is the concept of *information need*, which has proved intractable for the reason advanced by Wilson in 1981; that is, *need* is a subjective experience which occurs only in the mind of the person in need and, consequently, is not directly accessible to an observer. The experience of need can only be discovered by deduction from behaviour or through the reports of the person in need (p. 6).^[37]

Wilson's models of information behavior have evolved throughout the past several decades [^[2] #1213; 9 #1118; 37 #1]. The significance of his treatment of information need in relation to information seeking behavior is the holistic or ecological nature of his model, which situates information behavior in a person's contextual setting. In his models of 1996 and 1999, Wilson separated information need from motivation—recognizing that information needs are not always acted upon. Others, such as Bruce have considered information needs in terms of personal information management rather than as the motivating force behind information seeking behavior. The personal anticipated information need (PAIN) hypothesis describes a person's struggle to anticipate their future information needs while making personal information management decisions related to the storage and management of information.^[38]

As discussed, there is a growing body of research that addresses information behavior in a social context and within this, research on information need is addressed. Notable research studies include those by Fisher and colleagues regarding information grounds, Harris and Dewdney on battered women, and Chatman's stream on marginalized populations.^[32,39–41] As a motivating research question, Chatman discovered that the expression and development of information needs were largely influenced by social factors. In environments such as a prison, she found evidence that information needs were socially constructed^[32]—findings that were confirmed by Fisher et al., in their studies of information flow in informal, social settings, or information grounds. Savolainen's^[39] model of information seeking in the context of way of life (ELIS) also addresses information behavior in a social context. As described by Savolainen^[42] the ELIS model "was developed to elaborate the role of social and cultural factors that affect people's way of preferring and using information sources in everyday settings."^[42]

Information need is a central concept to virtually all information models. It represents the starting point and motivation that brings a user to engage in the process of information seeking. The definition of information need is allusive and may best be defined according to the meta-theoretical framework used to guide research.

CONCLUSION

Research on information needs has taken new, exciting directions since the mid-1990s for three primary reasons: (1) important foundational work on “needs” had been carried out thus enabling exploration into new forays; (2) researchers have becoming even more interdisciplinary than in the past, applying rich ideas from other fields to their work; and (3) the advent of the Internet and the World Wide Web along with other new information and communication technologies facilitated more and new information behaviors that are more easily studied than in the past.

Promising research directions include research conducted on community information needs.^[39,43,44] Research on nonpurposive information seeking is expressed as serendipity and information encountering.^[45,46] Recognizing the role of lay mediaries in the information seeking process in terms of not only searching for information but also helping others realize their information needs through such phenomena as imposed queries and gate-keeping.^[47] Lastly, research on the process of knowledge structure transformation on information need development all show promising signs of furthering our understanding of information needs from multiple perspectives.^[48]

There is still much to learn about information needs. In his 1981 article “On User Studies and Information Needs” Wilson attempted to “reduce confusion by devoting attention to the definition of some concepts and by proposing the basis for a theory of the motivations for information seeking behavior” (p. 3).^[2] Although the LIS field has learned a great deal about information behavior while its theoretical frameworks have matured, questions regarding the nature of information need and how it relates to motivation remain. There is great promise that given the new directions of the past decade and the renewed interest in factors influencing information need, some of these questions will be answered.

Information Needs and Behaviors of Diasporic Populations

Ajit K. Pyati

University of Western Ontario, London, Ontario, Canada

Abstract

Diaspora, which refers to the global and transnational spread of certain ethnic and religious groups, has been a reality for a long time. However, the increasing spread and ubiquity of new media technologies has in many instances accelerated the diasporic reality for many immigrant communities, facilitating transnational connections and senses of identity. In particular, the context of diaspora is affecting ways of approaching immigrant information behavior research. Specifically, diasporic information needs and behavior research takes account of the transnational information environments of these populations. Thus, immigrant communities are often part of rich, global information networks. New research is emerging which frames immigrant information research within a diasporic context, bridging local and global information needs and behaviors. Implications exist for rethinking concepts of assimilation, fostering cultural preservation and growth, and the development of enhanced social capital.

INTRODUCTION

In a world characterized by processes of globalization, both capital (often in the form of transnational corporations) and human beings increasingly traverse borders. The immigration of populations, often from the so-called “third-world” to the “first-world,” is a major characteristic of the modern age. The movement of human populations around the world is certainly not new, however, as mass displacements of people (both voluntary and forced) have occurred across the centuries. Thus, the African slave trade, which reached its peak in the eighteenth and early to mid-nineteenth centuries, is a prominent example of a forced and brutal migration of a population. On the other hand, however, middle-class immigrants from Asia and Eastern Europe who are working in the information technology industries in the West are examples of voluntary economic immigrants.

While the term “immigration” captures the movement of certain ethnic groups across international borders, the term “diaspora” refers to the global dispersion of various ethnic populations around the world. Diaspora is etymologically derived from the Greek word “diasperien,” which means “to sow or scatter seeds,” and has historically referred to displaced communities of people who have been dislocated from their native homeland though the movements of migration, immigration, or exile (p. 1).^[1] This term was originally applied to Jewish populations living in exile from their homeland, with later references to an African diaspora, accelerated by the slave trade. This term is now extended to refer to the global spread of a host of various ethnic groups, including Chinese, Indian, Haitian, Cuban, and Vietnamese populations, to name just a few. Thus, diaspora refers to a global spread of a population that transcends national boundaries, while

immigration focuses more specifically on communities living in a “host” or “adopted” land. Diaspora studies research is gaining in importance as a field of study, covering a range of disciplines in the humanities and social sciences.

Information needs and behavior research focus on the conscious efforts of individuals or populations to acquire information in response to needs or gaps in knowledge.^[2] The information needs and behaviors of immigrant populations have been studied to a modest degree in the literature of library and information science. Given the changing demographics of many Western countries and the increasing importance of immigration to the economic well-being of these countries, however, understanding the information needs and behaviors of immigrant groups is becoming an increasingly important endeavor.^[3] Immigrants are a diverse and heterogeneous group, and their information needs and behaviors differ based on a set of various economic, ethnic, and demographic factors.^[4] Research on immigrant information needs focuses on a range of issues such as settlement information, economic information, and information for cultural and civic engagement.^[4]

The context of diaspora is now being recognized in Library and Information Science (LIS), particularly in relation to the information needs and behaviors of immigrant communities. Diasporic information behavior research is most closely tied to diaspora research within the field of media studies. In the context of globalization, diaspora helps to situate the information environments of immigrant communities on an international scale, as the information realities of many immigrant communities stretch beyond the boundaries of Western nation-states. For instance, immigrant communities are often part of larger diasporic information and media markets, including

access to global satellite television and international Web sites.^[5] Thus, transnational information networks play an important role in understanding diasporic information needs and behaviors.^[6] This entry presents an overview of the current state of diaspora research within the context of LIS, a new area of research within the field, which extends the contours of immigrant information behavior research. The following sections discuss prominent themes in diaspora research, diaspora and media studies, immigrant information-seeking research, and the emerging field of diasporic information research.

DIASPORA RESEARCH: PROMINENT THEMES

The field of diaspora studies is a growing area of study, with coverage in fields as diverse as literature, sociology, anthropology, film studies, queer theory, area studies, and ethnic studies.^[1] Some of the leading theorists on diaspora include Arjun Appadurai, Homi Bhabha, Stuart Hall, Paul Gilroy, Lisa Lowe, and Aihwa Ong, to name a few. Diaspora studies is a diverse area, with a wide range of differing perspectives and viewpoints. Diaspora in fact is a contested term, with some scholars focusing on its liberatory potentials, while others are cautious about its limitations and abilities to transcend existing social and power dynamics.^[1] Diaspora does not, for instance, transcend differences of race, class, gender, and sexuality, nor can it be disassociated from these categories of analysis [7, as quoted in 1]. In certain cases, diasporic identities might be subject to hegemonic influence by dominant groups and elites, and can reinforce existing ideologies and power structures.^[8] Thus, while offering new possibilities for expressing transnational identity, diaspora is also subject to the same power structures and forces that shape other social formations.

Diaspora studies is related to the concept of globalization, but the focus is on the dispersion and movement of populations around the globe, rather than the movement of corporations and global capital. The following subsections will focus on a few prominent themes in diaspora research. The first subsection discusses in detail some of the differences between diaspora, transnationalism, and globalization. The next subsection discusses the related themes of hybridity, imagination, and identity—it is widely argued in the literature that diasporic communities often reside within *in-between spaces* across different cultures, which allows for a fluid and flexible sense of identity. The last subsection focuses on the role of diaspora in critiquing dominant views of the nation-state, as diaspora may allow for a certain *postnational* sensibility for people beyond the traditional rubric of nation-states.^[9]

Globalization, Transnationalism, and Diaspora

The importance of diaspora as a framework for understanding the information needs and behaviors of certain

ethnic groups cannot be discussed without reference to globalization. Globalization is seemingly the buzzword of the twenty-first century—while a concept that is complex and contested, a certain agreement exists about its occurrence and tangibility. Globalization, whether of the top-down, corporate-dominated variety,^[10] or in its more grassroots conception, is fundamentally concerned with the increasing interconnectedness of social, political, economic, and cultural relations in the world. This interconnectedness is manifested in global flows of capital and labor, especially with regard to immigration from the global “South” to the “North.” Globalization, however, often is associated with logics of cultural homogenization and the dominance of Western values and interests.^[10]

Diaspora, transnationalism, and globalization are related terms, but are not necessarily the same, however. As Brazil and Mannur^[1] discuss:

While diaspora may be accurately described as transnationalist, it is not synonymous with transnationalism. Transnationalism may be defined as the flow of people, ideas, goods, and capital across national territories in a way that undermines nationality and nationalism as discrete categories of identification, economic organization, and political constitution. We differentiate diaspora from transnationalism, however, in that diaspora refers specifically to the movement—forced or voluntary—of people from one or more nation-states to another [p. 8].

A difference between diaspora and transnationalism, therefore, is the distinction between the often impersonal forces of globalization and global capitalism, and the lived experience of migration and dispersion. Transnationalism, in its dominant version of global capitalism and global institutions such as the International Monetary Fund and the World Bank, is often associated with processes of cultural and economic homogenization.^[11] In contrast, some argue that a focus on diaspora emphasizes forces of cultural heterogeneity.^[9] Diaspora and the networks of people and associations across borders can be viewed as a form of “globalization from below,” in contrast to the top-down globalization characterized by large corporations and increasing homogeneity.^[15]

Hybridity, Imagination, and Identity

Diaspora is a contested term, with a range of political and cultural meanings. The nostalgic dislocation from a “homeland” has traditionally characterized concepts of diaspora, but increasingly differentiated meanings of the concept now proliferate.^[11] For instance, diaspora and the *diasporic identity* of these populations are often marked by hybridity and heterogeneity, in cultural, linguistic, ethnic, and national terms.^[11] Hybridity and heterogeneity thus often define diasporic identity, an identity that is not necessarily fixed and is often “deterritorialized” (p. 37).^[19]

For instance, Appadurai^[9] discusses deterritorialization in the following way:

As Turkish guest workers in Germany watch Turkish films in their German flats, as Koreans in Philadelphia watch the 1988 Olympics in Seoul through satellite feeds from Korea, and Pakistani cabdrivers in Chicago listen to cassettes of sermons recorded in mosques in Pakistan or Iran, we see moving images meet deterritorialized viewers [p. 4].

Thus, the process of deterritorialization is related to an internationalized sense of identity for many diasporic communities. Diasporic identity formation is a creative process that takes place often at the intersection of various nations and cultures.^[9]

Diasporic identity and consciousness is also a “work of the imagination” (p. 5)^[9] as diasporic communities endeavor to reimagine homelands and also articulate diverse and hybrid adaptations of cultural reality. Thus, diasporic identity and consciousness can be thought of on the one hand as a process of re-creating cultural spaces, but on the other hand as also part of an imaginary construction of identity. Benedict Anderson’s work^[11] on the role of print capitalism in the creation of imagined national communities provides a foundation for Appadurai’s work, as Appadurai extends this thesis to the role of electronic and new media for the creation of diasporic identity. Thus, according to Appadurai, the role of electronic and new media is important in facilitating these works of the imagination.^[9] These media sources and networks help in the process of diasporic identity construction and map out spaces for expressing this identity.^[5]

Appadurai’s framework for understanding the implications of globalization and new media for diaspora is influential in the field of diaspora studies. He lays out the following dimensions of this framework for understanding the new global economy in terms of “-scapes”: 1) ethnoscares (people who move between nations, such as tourists, immigrants, exiles, guestworkers, and refugees); 2) mediascapes (electronic and new media); 3) technoscapes (technology, often linked to multinational corporations); 4) financescapes (global capital, currency markets, and stock exchanges); and 5) ideoscapes (official state ideologies and counter-ideologies) (p. 25).^[12] These -scapes provide a lens to understand the disjunctions in the global cultural economy.^[12] All of these dimensions are global in nature, while at the same time diasporic communities develop their own local articulations of these dimensions. The focus on mediascapes has had the most impact on diasporic information behavior research. Appadurai^[9] further describes mediascapes as follows:

Mediascapes refer both to the distribution of the electronic capabilities to produce and disseminate information (newspapers, magazines, television stations, and film-

production studios), which are now available to a growing number of private and public interests throughout the world, and to the images of the world created by these media [p. 35].

In addition to Appadurai, Homi Bhabha^[13] discusses the notion of diasporic spaces, which is influential in the field of diaspora studies. He argues, for instance, that the movements of populations around the world have created spaces that are neither part of the “homeland” nor the “adopted country.” Bhabha^[13] discusses this in-between zone of diasporic communities as a “Third Space,” an area of identity articulation outside the homogenizing narratives of Western modernity. Bhabha discusses this Third Space as a way for diasporic communities to engage with and create new articulations of modernity. Beyond the case of diasporic communities, this Third Space of enunciation also problematizes the inherent originality and purity of cultures, as even Western cultures (despite claims to homogeneity) demonstrate hybridity.^[13] Thus, diasporic identity (and the concept of identity in general) is viewed as a hybrid and shifting concept, in contrast to notions of a *pure* identity.^[14] Diasporic groups are thus able to navigate a range of identity formations, depending on various local and global inflections.

Diaspora and the Narratives of the Nation-State

Another theme that occurs within the literature of diaspora is the disruption of the dominance of nation-states in identity formation and creation. Some scholars argue, for instance, that we are entering a stage of postnationalism,^[9] with the nation-state receding into the background, as transnational forces hold greater sway. As Braziel and Mannur^[1] state:

...diaspora forces us to rethink the rubrics of nation and nationalism, while refiguring the relations of citizens and nation-states. Second, diaspora offers myriad, dislocated sites of contestation to the hegemonic, homogenizing forces of globalization [p. 7].

The transcendence of the nation-state as a main shaper of identity is a theme that is echoed in much of the diaspora literature.^[5,9] Appadurai,^[9] for instance, argues that the United States needs to examine its understanding of immigration issues and multiculturalism. As he discusses in regard to the United States, “neither popular nor academic thought in this country has come to terms with the difference between being a land of immigrants and being one node in a postnational network of diasporas” (p. 171).^[9] The discourse of diaspora appears to challenge dominant narratives of fixed national identity and the primacy of the nation-state as a major cultural shaper. However, other forms of nationalism and ethnic identity may be privileged in lieu of traditional discourses of the

nation-state [15, as quoted by 5]. These nationalisms may be chauvinistic in nature or highlight particular politically charged and controversial notions of identity, as in the case of the imagined nation of “Khalistan” for Punjabi Sikhs in the 1980s (p. 36).^[12] Thus, diaspora may create different senses of imagined national identity beyond the nation-state.

DIASPORA AND MEDIA

This section provides a brief overview of prominent research in diasporic media studies. Appadurai’s work on mediascapes is influential in this line of study, and diasporic media research is closely related to diasporic information needs and behavior research. Electronic media are playing an increasingly important role in the development of diasporic consciousness as “moving images meet deterritorialized audiences” (p. 4).^[9] Recent scholarship on diaspora and media spans a wide range of ethnic groups and types of electronic media.^[5,14,16,17] For instance, Karim^[5] has edited an influential book which highlights some prominent research in the field of diasporic media studies.

In this edited volume, Manas Ray^[18] discusses the role that the Mumbai-based film industry of “Bollywood” plays in the identity construction of Fiji Indians. For this ethnic group, which has been displaced from the Indian “homeland” for several generations, Bollywood is playing a role as an information source in the construction of an imagined sense of identity and nationhood.^[18] Naficy^[19] discusses the role of “narrowcasting” in diaspora, how television programming for diasporic Middle Eastern groups can provide information and entertainment. In the case of Middle Eastern groups and other diasporic groups in general, both ethnic television (usually produced in the host country) and transnational television (media that is imported from overseas) play a role.^[19] DeSantis^[20] provides examples from the Latin American television environment in North America, as Mexican and Brazilian programming are gaining new audiences in this market. Thus, television can play an important role as a diasporic information source, both for purposes of entertainment and identity formation.

The Internet is also increasingly a space for negotiating diasporic identity and the sharing of diasporic information. Mandaville,^[21] for instance, discusses the role of the Internet in the creation of a virtual *ummah* (world community of Muslims) in the Islamic diaspora. In particular, Mandaville^[21] discusses how dominant discourses of Islam can be challenged by dissenting voices on the Internet, especially within the context of Western Europe and North America. A sense of virtual community amongst Muslims living abroad can be developed, and this identity often has local inflections and connotations.^[21] This ability for the Internet to provide a space for new articulations

of identity is echoed in the experiences of countless other ethnic groups. For instance, in the context of Greek populations, Tsaliki^[22] discusses how the Internet can embody Bhabha’s^[13] notion of the Third Space, as it can provide an “in-between space” between the nation and its diaspora, allowing for rearticulations of national narratives.

In addition, the work of Mitra^[23] on immigrant identities in “cybernetic space” discusses how Indian immigrants are interacting in online spaces in a process of identity formation. In the context of local, immigrant country spaces that may be threatening to an expression of immigrant identities (especially in a post-9/11 world in the United States), Mitra^[23] argues that online spaces offer an opportunity to re-create some of the physical places that have been lost for Indian immigrant communities. These examples highlight just a small portion of the growing literature on diasporic communities and their often empowering uses of the Internet.

Despite the liberating possibilities of the Internet and new media for diaspora and diasporic identity, research has also shown the potential for fragmentation, homogenization, division, and the replication of inequalities. In the case of the Indian diaspora, for instance, some scholars question the imposition of a monolithic understanding of Indian identity, often defined by Hindi language films and Hinduism.^[24] The reality of the Indian diaspora (and all diasporas in general) is that it is a multiplicity of diasporas, influenced by factors such as class, religion, language, and country of residence, to name a few factors.^[25] Issues of religious extremism and ethnic chauvinism are also a concern in the discourse of diasporic media research. Economic and technological elites can reproduce understandings of religion and culture that may not reflect the diversity of diaspora.^[8] In terms of the Indian diaspora, research has shown that Hindu nationalist discourses are being privileged, along with middle-class Hindu notions of Indian identity.^[8,26] However, the Internet can also provide spaces for marginalized voices to contest the hegemony of these dominant narratives.^[8,21] Thus, information and communication technology (ICT)-mediated diasporic information sources can both disrupt and reinforce hegemony.

IMMIGRANT INFORMATION-SEEKING BEHAVIOR RESEARCH: KEY THEMES

The reality of globalization and diaspora is affecting information seeking research as well, although it is often not explicitly referenced or referred to as such. This intersection with globalization is manifested in research focusing on the information-seeking behavior of immigrant groups. The cultural diversity of information seeking behaviors and needs is now widely recognized as an important area in the field. In the West, and especially in a post-9/11

world, immigration (both legal and illegal) and discourses about immigration are often center stage in political, economic, and national security debates. Immigrant information-seeking behavior research is related to and has a longer history than diasporic information behavior research, and this section discusses some of the main themes in this research area.

The information needs and behaviors of immigrant groups, as various studies have shown,^[4,27–29] often differ from the information needs and behaviors of dominant and mainstream groups in society. Depending on the immigrant community and variations in economic status, information needs vary, covering a wide range such as basic English literacy information, information about basic living skills in the new country to information about maintaining cultural ties to the home country, to name a few. The implications of these types of studies are important in the better design of information services and ICT-enabled information resources that meet these particular behaviors and needs. While immigration occurs at all socioeconomic levels in the United States and other Western countries, particular concerns arise regarding the needs of low-income immigrants and the reality of *information poverty* and the *digital divide*.

A valuable body of work dealing with immigrant information-seeking behavior already exists, and the work of Metoyer-Duran^[27] on ethnolinguistic gatekeepers is an important example. Gatekeepers in ethnolinguistic, minority communities in the United States, according to Metoyer-Duran^[27] “act as agents of acculturation when they disseminate information within their communities” [p. 320]. Thus, gatekeepers are key information agents and disseminators within these communities. She identifies two major “domains” in which gatekeepers operate—the cognitive and affective. She describes the cognitive domain in relation to established theories of learning that promote the hierarchical acquisition of knowledge, while the affective domain is concerned with the gatekeeper’s cultural orientation toward information needs and use. While the details of these domains are not important to this discussion, the subsequent “profiles” that Metoyer-Duran derives in relation to these domains has important consequences for understanding the information seeking behavior of these groups. She defines six different profiles for gatekeepers as: 1) impedor; 2) broker; 3) unaffiliated gatekeeper; 4) affiliated gatekeeper; 5) information professional; and 6) leader/executive.

Another strand of research in immigrant information seeking is the work on “information grounds.” According to Fisher, information grounds are “environment(s) temporarily created when people come together for a singular purpose but from whose behavior emerges a social atmosphere that fosters the spontaneous and serendipitous sharing of information” (p. 811).^[30] The key qualities of “information grounds” are their temporality and existence in “nontraditional” information environments. Examples

of information grounds include restaurants, hair salons, buses, medical offices, and grocery store queues, to name a few. For example, this particular kind of information grounds research is found in “Information Grounds and the Use of Need-Based Service by Immigrants in Queens, New York: A Context-Based, Outcome Evaluation Approach”.^[31] The researchers in this article focus on exploring how programs in literacy and coping skills run by the Queens Borough Public Library (QBPL) in New York City might function as information grounds. The researchers conclude that these programs constitute a “grand context,” and a rich information grounds for immigrant populations. Some gains achieved in these programs include improved coping skills and technology skills, and better preparation for employment. Other immigrant information grounds research points to the strength of interpersonal networks as sources of information, as the choice of which information ground to visit is related to factors such as ease of communication and perception of increased reliability of sources in these environments.^[28] Also, given the language, cultural, and economic barriers and the deep extent of everyday needs that some immigrant communities face, interpersonal sources of information are often preferred sources.^[28]

Other prominent studies on immigrant information behavior include Chu’s^[29] work on immigrant child mediators (ICMs). This study focuses on how immigrant children can serve as cultural, linguistic, and information intermediaries for immigrant parents. Chu provides suggestions for librarians on how to effectively address the needs of this group. While interpersonal networks and the use of intermediaries are important in the discussion of immigrant information behavior, the role of social capital is also important in this area of research. Caidi and Allard^[4] discuss how information access for immigrant communities can become part of developing the social capital of these communities. Social capital is a term used in various literatures, and according to Putnam,^[32] it is related to “social organization such as networks, norms and social trust that facilitate coordination and cooperation for mutual benefit” (p. 67). Social capital is related to enhanced connections to resources for immigrant communities with the potential for enhanced social inclusion and civic participation.^[4] The next section extends these ideas into the context of diasporic communities.

DIASPORIC INFORMATION BEHAVIOR: EXTENDING IMMIGRANT INFORMATION RESEARCH

While many immigrant communities in North America and the Western world are part of rich and layered diasporic communities, much of the research in LIS and information studies does not yet reflect this reality. One of the first major studies exploring the role of diaspora in

immigrant information-seeking behavior is Srinivasan and Pyati's^[6] article in the *Journal of the American Society for Information Science and Technology*, entitled "Diasporic Information Environments: Reframing Immigrant-Focused Information Research." These authors argue that studies of immigrant information behavior need to be situated within the dynamic contexts of globalization and diaspora. Specifically, they propose a methodology for understanding diasporic information behavior through the lens of what they term a *Diasporic Information Environment Model* (DIEM).^[6] This model links the local, place-based information environments of immigrant communities with the global, transnational ICT-mediated information environments of these groups. Methodological frameworks such as reflexive ethnography, social network analyses, and community-based action research are discussed as ways to develop local and global analyses of diasporic information behavior.

Srinivasan and Pyati^[6] draw in major part from the work of Arjun Appadurai, one of the leading scholars in theorizing ICT-mediated diasporas. He talks about the increasingly important role of ICTs and ICT-enabled technologies in the process of maintaining and creating diaspora, helping to further create "works of the imagination."^[6] As globalization becomes increasingly defined and mediated by ICTs, immigrant groups and their information-seeking behavior are being shaped by diasporic forces enabled by information technology.

The complex association between diasporic groups and ICTs has led to a concept of e-diasporas that actively utilizes ICTs to achieve community-specific goals.^[6] A scenario of moving migrants has made e-diasporas critical for the formation and sustenance of community for immigrant groups.^[9] Appadurai argues that nation can be formed in cyberspace, and often cyberspace serves as the sole means of providing a sense of aspiration and hope to placeless migrant populations.^[33]

The DIEM of Srinivasan and Pyati^[6] works to bridge local and global information environments by recognizing the transnational and fluid identities of immigrant and diasporic communities. Thus, these authors acknowledge the importance of local information grounds and local networks, but also recognize the increasing importance of diasporic Web sites and transnational networks for information.^[6] The authors illustrate this bridging of local and global information sources through a discussion of the Somali diaspora. Srinivasan^[34] has conducted research with Somali refugee communities in Boston, noting that this community is not isolated, as it is in constant communication with refugee pockets in other parts of the United States, Kenya, and Italy. Srinivasan and Pyati^[6] discuss how this diasporic community's needs can be effectively studied by the DIEM. For example, they discuss how social network analyses can identify the transnational information networks of this community, which can result in better community service models. The DIEM also

emphasizes community-based research which can help engage local communities to address and articulate their own information needs. The major difference between diasporic and immigrant information behavior research, as identified in the work of Srinivasan and Pyati,^[6] is an emphasis and recognition of the globalized nature of information resources for certain immigrant communities. The understanding of connections of immigrant communities to different information networks and resources beyond the local environment is a contribution of a diasporic perspective. Implications exist for the preservation and growth of culture,^[6] and this perspective emphasizes the sometimes hidden information assets of immigrant communities.^[33]

Related to the diasporic information behavior perspective is the importance of social capital and social inclusion. Caidi and Allard^[4] discuss the role that information access can play in furthering these ideals. These authors emphasize an understanding of social inclusion that is not related to social cohesion, but rather makes visible and breaks down barriers that prevent full participation in new host countries.^[4] According to these authors, "social inclusion values diverse identities and fundamentally questions both the process and result of social inclusion" (p. 313).^[4] Thus, social inclusion can be framed as a way for immigrant communities to embrace diasporic identities, while also taking part in local civic life. This orientation can have implications for information services to these communities as librarians and other information service providers can be more aware of the global and diverse nature of immigrant information environments. Thus, information for social inclusion and cultural preservation may come from diasporic and global sources. As the world becomes more globalized, concepts such as citizenship and assimilation are being problematized.^[9] Meeting the information needs of diasporic communities largely overlaps with the domain of traditional immigrant information services but brings the added perspective of providing information for global citizenship and identity. This perspective acknowledges the lived reality of diasporic communities and recognizes the Third Space^[13] of diasporic identity, a fluid and hybrid space of agency for these communities. An increasingly globalized and arguably *postnational* world may spur increasing research focused on diaspora within LIS.

CONCLUSION

This survey of the information needs and behaviors of diasporic populations has highlighted the increasing importance of ICTs and new media in the creation of "e-diasporas." Diaspora, which refers to the global and transnational spread of certain ethnic and religious groups, has been a reality for a long time; however, the increasing spread and ubiquity of new media technologies has in

many instances accelerated the diasporic consciousness of many immigrant communities. This discussion began with a brief overview of what diaspora means in the context of globalization, and how it is affecting ways of approaching immigrant information behavior research. Specifically, studying the information needs and behaviors of diasporic populations takes into account the often transnational information environments of these populations.

While the information needs and behaviors of diasporic populations mirror key ideas and concepts in standard immigrant and ethnolinguistic minority information behavior research (e.g., gatekeepers, information grounds, importance of personal social networks, etc.), diasporic information needs research is adding a globalized perspective to understanding these information needs and behaviors, providing a space to understand the global-local tension in immigrant information environments. For instance, immigrant groups are increasingly looking toward transnational and ICT-mediated sources of information not necessarily tied to a particular location. Due to the increasing influence of new media technologies, a diasporic consciousness and identity often accompanies information resources for these groups. New research that specifically looks at the relationship between the global and local nature of immigrant information environments is beginning to appear in the LIS literature,^[6] and it is likely that more research will continue to emerge that takes into account the larger context of globalization and diaspora.

Information Needs and Behaviors of Populations in Less Developed Regions

Innocent I. Ekoja

University Library, University of Abuja, Abuja, Nigeria

Abstract

The information needs of the peoples of the developing regions are for work-related activities, leisure, consumption, and daily survival. Due to low literacy levels and ignorance about other sources, the general information-seeking behaviors include passive quests for information and heavy reliance on opinion leaders, rumors, and oral sources, with the library often the least preferred source for information. Even with an emphasis on the seeking of information for utilitarian purposes, people generally have not adopted the habit of utilizing information resources such as libraries and information centers in their work, life, and study. Due to their urban locations, distance and poor information infrastructures, libraries and information centers are not patronized frequently and regularly by many potential users, who instead resort to the use of their own personal collections and individual contacts. In the face of poor retrieval devices, browsing is the most favored approach to determine the relevance of materials to be consulted. In some instances people use information outside that for which they express interest. The predicament of libraries and information centers in developing regions is made worse by lack of local content, the failure to develop indigenous knowledge systems, and especially the advent of information and communication technologies (ICTs). The latter have brought about further lower patronage because most libraries and information centers cannot afford the ICTs. Finally, the inefficiency of general municipal services makes the information seeker exert more effort and spend more time to access information than might be expected in developed countries.

INTRODUCTION

This entry will provide an understanding of the information needs and behaviors of people in developing regions. “Information needs” refers to the information that people require to conduct their businesses and live their daily lives. “Information behaviors” are the tendencies and approaches exhibited by people while seeking out information.

All human beings need information, regardless of where they live. It is required for individual growth and development, and by extension, societal growth and change, too. Information is needed both for personal, social and/or work-related activities of individuals and for development of societies and states.

As information-dependent organisms, human beings have discernible ways of looking for information to meet their information needs. However, for reasons to be discussed, access to information through libraries and over the Internet, while increasingly common in the developed world, is limited in developing or underdeveloped countries. Rather than drawing on these sources for information, people in developing countries often use a variety of other information-seeking resources that are more readily available.

THE CONCEPT OF DEVELOPING COUNTRIES

Based on their economies, the World Bank has classified the countries of the world into low, middle, and high income economies. According to the Bank, “low income and middle income economies are sometimes referred to as developing economies” or countries.^[1]

The developing countries of the world are those with low standard of living, a weak industrial base, and a generally low human development index score. Among the outstanding features of developing countries are widespread poverty and low capital formation. The developing countries are found especially in sub-Saharan Africa, Asia, the Pacific, Latin America, the Caribbean, etc. The factors responsible for the under-development of these countries are many and are subsumed under social, political, and economic considerations. Among the many political and economic considerations is improper access to education and information.^[2]

FRAMEWORK OF THE ENTRY

The framework for this entry is based on an adaptation of Ranganathan’s categorization of human knowledge.

Ranganathan categorized human knowledge using concepts of “personality,” “matter,” “energy,” “space and time” (PMEST) (p. 452).^[3] This categorization also can be used to understand human information-seeking behavior by drawing the following analogies:

- “Personality” includes individual information seekers and individual information-seeking behaviors occurring in the information environment, both of users and managers, their social networks, etc.
- “Matter” includes the information and information resources, access systems and technology.
- “Energy” entails the problems/goals, processes and tasks undertaken in the course of information provision.
- “Space” entails the work space, organization, country, or geographic unit.
- “Time” entails episodes, intervals, and total time needed for information to be accessed.

“PERSONALITY”: INDIVIDUALS AND INDIVIDUAL INFORMATION SEEKING IN THE DEVELOPING WORLD

At the most basic level, one might simply explore the ways individuals seek information, which could be through any or a combination of the following ways (p. 3):^[4]

1. Experiment(s) or adopting a trial and error approach.
2. Asking colleague(s) or discussing with him/her (them).
3. Consulting personal collections for relevant information sources.
4. Observing nature or environment for needed information.
5. Consulting library/information centers for information either through self-help or consulting the librarian/information professional.

Information-seeking behaviors vary considerably from one individual to another according to age, gender, level of education, occupation, location, religion, culture, etc. It is very difficult, if not impossible, to identify common information-seeking behaviors for all the peoples of the developing regions of the world. This entry therefore will not attempt to identify common individual information-seeking behaviors in different countries and cultures of the developing world.

Rather, this entry will explore some general parameters influencing information-seeking behavior of types or groups of individuals in developing countries. Information-seeking behavior is the noticeable, and in some instances, the unnoticeable traits individuals exhibit or ways they adopt in the course of seeking out needed

information. It is the purposive seeking for information as a consequence of a need to satisfy some goals.^[5] Information behavioral traits would be exhibited in the course of passive attention, passive search, active search, or on-going search for information (p. 433).^[6] Information-seeking behavior is therefore both a function of recognition of one’s needs for information, and knowledge of, availability of, and ability to make use of information services and resources to meet ones perceived information needs. We will consider parameters affecting meeting of the information needs of four types of individuals found in developing countries: students, professionals, farmers, and artisans. For all four groups costs, quality, or availability of information resources such as libraries, information centers, and some information networks more commonly accessible in more developed countries (e.g., professional conferences) limit their information access and contribute to their use of alternative means to obtain information.

There are millions of students engaged in academic pursuits or the pursuit of professional qualifications in the developing countries. Primarily, they require or need information to support or facilitate their academic pursuits. They would also require information for daily survival, such as information on where to get access to health care delivery, foods and drinks, clothing, spiritual needs, etc. Even though there are millions of such students, their social/professional networks are limited because of the constraints of economic resources and technological considerations. They are, therefore, hardly ever able to attend conferences, whether international or local, just as they hardly ever subscribe to journals, newsletters, etc., on their own. Due to high costs, they cannot subscribe to the membership of learned societies on their own either, even in situations where they are offered student rates. Students in developing countries are therefore more dependent for information than those in developed countries on school or university library resources that are often much poorer in quality, breadth, depth and being up to date than those in developed countries—or on other students and professors or teachers with whom they are in direct contact.

Professionals in the developing countries, as in the developed countries, include engineers, health care practitioners, legal practitioners, teachers, administrators, scientists, etc. Professionals require information to support their respective practices, and for their day-to-day living as well. Professionals in developing countries aspire to and do maintain social/professional networks, which afford them the opportunity to attend local and international conferences to discuss and exchange ideas with colleagues; subscribe to journals and newsletters; and subscribe to the membership of learned societies. However, owing to economic and technological constraints, among other reasons, most of them are unable to develop their social/professional networks to be able to acquire the needed material for research and other purposes. This contrasts with the situation of their counterparts in the developed world who

can and do develop and sustain such networks. There are, for example, professionals in the developing countries who, because of inadequate remuneration, cannot afford \$100 a year to initiate and retain membership of a single learned society. Some other professionals are unwilling to pay that much even if they can afford it because of competing needs for the money. In fact, in Nigerian universities, the highest paid professors are entitled to only \$300 a year for learned societies and \$600 for journal allowances. These amounts can hardly pay, on the average, for more than two learned societies and two journals from abroad. Due also to poor institutional funding, professionals in developing countries can hardly attend international conferences either, except in the few instances that they are sponsored by international organizations. In general, professionals in developing countries have fewer social/professional networks than their counterparts in developed countries because of these obvious limitations.

The farmer, artisan, and other less skilled workers also require information to further their practices and for their daily survival. It is probably with this category of information seekers that there would be the most major differences in terms of information needs and seeking behaviors when compared to their counterparts in the developed countries. This is so because of the big disparity in the levels of education of farmers, artisans, and less skilled workers in developing countries. In fact, in the developing regions, the majority of farmers, artisans, etc., are generally people with little or no education. Because of their low levels of education and general lack of exposure to a variety of information resources, they may not know how to go about meeting their information needs, or even if they know, they tend to wait passively for their information needs to be met instead of taking proactive measures to meet them.

Another big drawback for farmers, artisans, and less skilled workers is the lack of information in the language or form they would be able to access. Many of the developing countries, especially those in Africa have multi-ethnic groups with their own languages, yet the libraries and information centers provide information mainly in colonial languages such as English, French, Spanish, Portuguese, German, etc. Even then, libraries and information centers are available much more often in urban areas than in rural areas.

“MATTER”: INFORMATION AND INFORMATION RESOURCES IN DEVELOPING COUNTRIES

For the developing countries of the world, just as for the developed countries, information ought to be available to support the needs of the people for career-related activities, consumption, leisure, etc. Such information is available from a number of sources. Some developing countries have acknowledged the need for and attempted to provide

information resources to their populations. For example, Cai and O’Keefe (p. 23)^[7] report that both scientists and farmers in China have access to information through agricultural journals. It was also reported of China that the Management Data Team and the Library Resource Team disseminated information to village people, including farmers (p. 70).^[8] The latter effort was funded by the International Development Research Centre based in Canada. In contrast, in the Philippines urban Filipinos were better served than their rural counterparts (p. 10).^[9]

As shown by the above cases, there are a few instances of other developing countries where information is readily available, especially to urban populations. In general terms, however, most of the developing countries are both information-poor and information-starved. They are information-poor because they do not experience the kind of information flood experienced by the developed world. They are information-starved because they do not have the means to acquire the materials and infrastructure that contain needed information, or the economic resources needed to pay personnel to acquire, organize, and maintain access to the information. Developing countries, therefore, in most instances have to wait for donations, and those donations often provide outdated or non-relevant information resources.

In the developing countries, much like the developed world, current information for ready application is required. The information resources available to the populations of the developing world include print but also non-print materials, including databases (both online and offline). Electronic databases are available for use in the few libraries and information centers that have been automated and/or digitized. Where they exist libraries and information centers are located mainly in urban and semi-urban areas, with the implication that rural dwellers often do not have access to the resources to meet their information needs. Book mobiles (whether motor vehicles, boats, donkeys, etc.) are not as popular as they used to be in the past because they are little encouraged.

Information access systems in the developing countries are not well developed and coordinated because of the lack of the wherewithal of individual libraries to develop them, which is made worse by their failure to enter into cooperation and collaboration. The instances of cooperation and collaboration, where they exist, are few. This is even made worse by the fact that in most countries of the developing world, the necessary information and communication technologies (ICTs) and infrastructure required for information handling are not available.

Another issue is that most information professionals lack the necessary and requisite ICT skills. Inadequate training and human resource capacity was identified as a problem threatening the continued existence of the rural knowledge centers (RKC) in East Africa. This lack of capacity is not limited to ICT use, but there is a general lack of human resource capacity to manage even

conventional information resources and services in the developing countries such that they can meet the information needs of the communities they are meant for.

Recently and increasingly, however, there has been a considerable measure of investment in ICT acquisition and usage in many parts of the developing world, especially in rural communities, provided through international donors. On this score it has been observed with regard to East Africa that:

Rural knowledge centers, also known as community telecenters, are becoming a popular model for delivering ICT in rural areas, especially in developing countries where information and communication facilities are limited. The past decade has witnessed an explosion in projects that apply ICTs to support socio-economic development (p. 145).^[10]

These RKC include simple telephone shops, market information centers (MIC), market information prints (MIP), multipurpose community telecenters (MCT), etc. The MICs and MIPs are a creation of the Kenya Agricultural Commodity Exchange Limited, aimed at assisting small scale farmers with up-to-date market information services such as good prices for their produce and where to sell and buy at such prices, commodity stocks, etc. The ICT components of the MICs include computers and mobile phones, which farmers use to access current information. From the MICs, information is downloaded and distributed to the MIPs every market day (p. 15).^[11]

The multipurpose community centers are the most sophisticated of the RKC. Their services include telephony, Internet searching, satellite broadcasts for radio and video shows, fax, e-mail, etc. Using the examples of MCTs in East Africa, located specifically at Nakaseke, Buwama and Nabweru in Uganda; and Sengerema in Tanzania, it was reported that these centers undertake a number of projects that offer information on agriculture, education, health, and indigenous knowledge (p. 145).^[11] The information services deriving from these projects profoundly affect the ways of life of their host communities in several ways. These include opportunities for income-generating activities for farmers and local entrepreneurs who search the Internet for information on markets and agrochemicals, updating professionals with information in the fields of work as well as advertisements for job opportunities, and providing access to learning resources for students.

Despite these recent advances and occasional successes, the general prevailing practice in most developing countries is that ICT use has not impacted on information provision in a widespread way. Apart from the centers often being sparsely used, the general lack of much ICT infrastructure, replacement/update capacity, and trained personnel remain daunting challenges.

Another reason is the failure of most developing countries to develop their indigenous knowledge systems (IKS), which would have complemented the information coming from western knowledge systems (WKS), most of which emanate from the developed countries. It is observed of this situation that information flows in developing countries are segmented, divisive and uncoordinated (p. 2).^[12] Although it may arrive late (and already outdated) in printed form, WKS information is much of what can currently be obtained over the Internet and through ICTs. Professionals such as medical doctors in developing countries might be able to obtain WKS information about disease treatment, yet would also require IKS information about the traditions and cultures of the populations they serve in order to serve them well. Otherwise, if WKS information services offend the sensibilities of the populations served, they might not let themselves be served. It was reported of health workers in Upper East Region of Ghana that they required information about the beliefs, taboos, festivals, etc., of the people to be able to deliver acceptable medical practice to them (p. 367).^[13] Although developing countries have been slow in making IKS information available through channels such as libraries and information centers, indigenous knowledge items often remain available through rich oral traditions, ceremonial practices, etc. These oral traditions and active practices remain a positively valued alternative source for obtaining a wide variety of information.

“PERSONALITY” AND “MATTER”: THE INTERPLAY OF INFORMATION AND INFORMATION RESOURCE AVAILABILITY AND THE USE OF ALTERNATIVE INFORMATION-SEEKING BEHAVIORS

In most developing countries, professionals like engineers, scientists, technologists, medical doctors, pharmacists, etc., are unable to have most of their professional work information needs met because of the many factors reported in the last entry. A study conducted on the information needs of scientists and technologists in Nigeria revealed that libraries and information centers were unable to meet their information needs due to poor stocking and staffing. Current journals and databases lack good retrieval systems and interlibrary loan facilities. The other shortcomings included inadequate information sources and the poor orientation of library and information center staff to responsive reference services (p. 137).^[14] This study was conducted in the 1990s but the situations have generally not changed even with ICT availability, which for most libraries and information centers in the developing countries, is still a mirage. It is instructive to mention here that the Academic Staff Union of Nigerian Universities, which in 1991/1992 went on strike for over 6 months due to poor facilities, including libraries, in Nigerian

Universities went on strike again for several months in 2007 because the state of these facilities had deteriorated.

In the course of pursuing his academic or professional education, an average African scholar maximally exploits the limited available learning material to enhance his chances of acquiring the desired certificate(s). For him, therefore, knowledge or information is hardly sought after for purposes other than utilitarian. This is with the consequence that educated Africans, after acquiring certificates from educational institutions and professional bodies, hardly read outside newspapers and magazines. Since few people read for the sake of esthetics, it follows too that information or knowledge for esthetic purposes is hardly sought after. This situation is encouraged by the tantalizing rich oral culture to which many people turn to derive exciting and pleasurable experiences. Instead of turning to novels and other sources of information, whether print, electronic or otherwise to seek information that keeps them entertained; such entertainment can be derived from the happenings in the immediate environment(s).

Even as it was reported that the increased use of the Internet was bringing an end to the two-step flow of information seeking (p. 660)^[15] in some parts of the world, the two-step information-seeking approach still thrives very much in developing countries. The two-step information-seeking approach is a situation in which a person obtains information from friends and acquaintances who, in an earlier first step, had obtained such information from some other source. This approach still thrives in developing countries because the Internet is not readily available, especially to rural populations.

Another catalyst for the two-step flow of information seeking is the gregarious nature of the populations in developing countries, especially in Africa and Asia. This also promotes the use of oral sources by information seekers, including reliance on opinion leaders for information. This was acknowledged in a study of Indonesian farmers, who, it was reported, relied on opinion leaders and those with higher socio-economic status to get information about pest management (p. 4).^[16] The same is also true of many other settings in developing countries where community members rely for information on chiefs, community leaders, pastors, imams, and others with higher socio-economic status.

Related to the issue of two-step information seeking is that of rumors, which is prevalent and relied upon in Africa because of the propensity of African governments and their agencies to suppress information (p. 5).^[17] Rumor is not relied upon as sources of information only in Africa but also in many developing countries where dictatorial governments suppress information. In this situation, information, which one might expect to be readily available, is deliberately withheld, thus giving room to rumor peddling.

Another big barrier to the use of libraries or information centers by many people in developing countries is that

in making information and information resources available, consideration is not given to local languages, visual orientation, and the use of voice interfaces for populations that are to a very big extent illiterate. Because of this (both conventional illiteracy and ICT illiteracy), most of the populations for whom information services are meant are unable to use them, especially in the rural areas. A study on the information needs of community-based organizations indicated that most community development projects and social programs failed because information about them did not reach the people in the form or language that they understood (p. 34).^[18] This is also true of library and information services.

These are some of the problems facing information diffusion and use in many developing countries. A typical case is with regard to the developing regions of China of which it was reported that most citizens had not adopted the habit of utilizing information resources in their work, life, and study because of their low literacy levels.^[19] The developing regions of China are still better off than most other developing parts of the world because this same report indicated ICT availability to the rural Chinese, who with their ICT literacy, found the use of the Internet popular. The use of the Internet among them for information and services was, however, found to be detrimental to the patronage of reference services in public libraries, which service was obviously on the decline.

The library in most developing countries is the least patronized when users seek to meet their information needs because of irrelevant materials in terms of their language(s), form(s), and up-to-dateness. The language in which information is made available is very important, else people would be unable to use it. For example, for a setting where Kiswahili is the spoken and written language, materials provided in the English language would almost be useless. Similarly, where people are illiterate, print materials like books, journals, etc., would not be required to access information.

There is also the problem of lack of local content that meets the local and immediate information needs of the members of the communities where libraries and information centers are located. The situation is made worse by the failure of information services providers to consult with potential users to determine their information needs, and the failure still to monitor these needs regularly to be able to respond to changes. The result is that libraries and information centers are not providing services that users require.

Another major barrier to information needs and seeking behaviors of populations in the developing regions of the world is that information seekers more often than not use information other than that which they expressed a need for. It was observed in an Indian community that: "The information people usually say they need was not always what they end up using. In the M.S. Swaminathan Pondicherry Project, for example, male farmers originally

said they needed information about agriculture. In fact, their largest usage of village info-kiosks was to get information about government programs.”^[20]

The situation in India could be associated with the finding that:

Observing human information seeking has demonstrated that people do not always choose actions that would lead them to the optimal result. For example, they may bypass the most knowledgeable information provider to ask questions of someone they know. In fact, the typical findings of information-seeking studies in various settings indicate that accessibility of information is the key factor involved in what sources people select, and that interpersonal sources are preferred over other channels (p. 661).^[15]

“ENERGY,” “SPACE,” AND “TIME”: BARRIERS IN OBTAINING INFORMATION TO MEET INFORMATION NEEDS AND IMPACTS ON INFORMATION-SEEKING BEHAVIORS

There are a number of barriers to obtaining information that meets information needs and seeking behaviors in developing countries. These include outright non-availability of information and the information resources that meet the needs of users; availability of inappropriate information, and information resources; non-awareness of the information and information resources that are available; lack of time for searching for information and for learning how to use an information source; lack of the hardware and/or software with which to retrieve information; distance from users’ home to points of information, etc.

These problems have been observed to be setbacks to the free flow of information right from the source through the media to users, and have economic, social, environmental, and infrastructural dimensions (p. 5).^[15] The economic problems of information seeking relate to cost as it affects information carrying media, time, and labor. The general poverty of the developing regions makes it near impossible to develop the information infrastructure that can make information available to meet the needs of the people. Another major factor accounting for poor information services in developing countries is that they compete with other social services provision like roads, water, energy, etc., for which the people have a preference. Apart from the existence of only a few well-developed libraries and information centers, inadequate ICT development and outright lack of it is also a big factor militating against access to information.

The library and information systems are therefore not well developed to meet the information needs of users. This is especially true of the rural areas because library and information services providers, including telecommunications operators prefer to offer services in urban and semi-urban areas. Due to the poor library and information

systems, many professionals rely on their limited personal collections, and the few who can afford it own computers with Internet access. Those who cannot afford it have a Herculean task accessing desired information or are even unable to access it.

Compared to the developed countries, the information seeker in developing countries spends more time and exerts more effort in accessing the required information, which, in some instances, even after rigorous searching, is still not available. This is so because in the first place information facilities, as well as retrieval devices to aid his searching, are often just not available. The scarcity of retrieval devices makes browsing the most favored way to seek for information. It was observed with regard to the knowledge centers in East Africa that one difficulty in ensuring that they become sustainable is the lack of capacity to use ICTs to access and apply relevant information to solve problems (p. 150).^[17] This difficulty does not apply to East Africa alone but generally to most of the developing countries because of inadequate training opportunities and poor human capacity to use ICT to access information. The situation is such that it is not just the users alone, but even managers of information systems who often lack the capacity to manage information using ICTs in such a way as to produce the information that users need. Apart from their financial constraints to subscribe to information carrying media on CDs, VCDs, DVDs, and online, many information professionals in developing countries are unable to access open source materials, which can address the information needs of those they serve, due to this lack of human capacity.

Again because of the failure of municipal services provision, the information seeker spends 2–3 times over and above the time and effort he would have required to access information in better-supplied areas. An example is that in trying to access information on the Internet, power outage may be experienced, which will lead to the suspension of the exercise. Power may not be restored until some hours later, only to be interrupted again as the renewed effort to access the information commences. This may go on and on until the seeker succeeds in accessing the required information after several attempts. This makes information seeking more expensive in terms of time and labor, apart from the frustrations encountered. The prevailing poverty also makes access to information very difficult because generally most members of the populations of developing regions are unable to own information resources (books, computers with Internet connectivity, subscribe to journals, etc.) or even pay for Internet access in business centers that can enable them access the information that meets their needs.

Related to the problem of poor utility or municipal services is that of gasoline scarcity and cost that helps limit people’s ability to reach libraries or information centers. A lot of time, effort, and cost go into fueling own vehicles or boarding public transport that in the end those

who would normally seek after information to meet their needs are unable to do so.

Another major problem is the distance between the residences of information seekers and the points of information services. Such distances affect the frequency and regularity with which information is sought after and used in developing countries because of the time and cost involved. There are other activities such as social, religious, etc., competing for the time that would ordinarily have gone into the use of information. This is especially worse for women and girls because of their disadvantaged position, and the fact that they are saddled with most of the household chores.

CONCLUSION

Information is of strategic importance to the peoples of the developing regions. It is very difficult, if not impossible, to identify common information needs and behaviors for all the peoples of the developing world. However, the problems they face in the course of accessing information to meet their needs have much in common.

The issue of information needs and behaviors of populations in less developed regions was addressed from the perspective of an adaptation of Ranganathan's PMEST categorization, which stands for personality, matter, energy, space, and time. The information seekers in the developing regions include students, professionals, artisans, farmers, etc., whose limited social/professional networks constitute one of the problems for their failure to have their information needs met. Some of the potential information users have very little education, or are even outright illiterate and ignorant, and therefore do not know how to go about meeting their information needs, or at best wait passively for information to be brought to them.

It is only in a few parts of the developing countries that information infrastructures are available to meet the needs of the populace. The majority of the developing countries experience information starvation and information poverty, lack of commitment by concerned authorities to provide effective information systems, and failure to develop IKS to support WKS. The two-step flow of information is the vogue due to vast oral sources, which along with the suppression of information by authorities, is also associated with reliance on rumors, opinion leaders, and community leaders.

The information access systems are generally not well developed, and part of this is explained by the fact that most information professionals lack the requisite skills, both conventional and ICT, for the handling of information. Where ICTs have made in-roads, it is most often with the assistance or intervention of western donor agencies, and in such cases the professionals manning such libraries and information centers have the capacity to offer services

using ICTs because the training of personnel is one of the components of such interventions.

The barriers to obtaining information to meet the needs of the populations of the developing regions are many. They include outright non-availability of information and the information resources that meet the needs of users; availability of inappropriate information and information resources, non-awareness of the information and the information resources that are available; lack of time for searching for information and for learning how to use information sources; lack of the hardware and/or software with which to retrieve information; distance from users' homes to points of information; and other factors associated with the problems of daily life in developing countries.

Although the challenges are great, all hope is not lost for the populations of the developing regions to have their information needs met if only their governments and other funding authorities will rise up to make education and information provision priorities. When they do this, it will encourage western donor agencies, which are already doing much to facilitate access to information in the developing regions, to do even more. Another important thing to do is to encourage the development of IKS to complement WKS in the developing countries.

Information Policy: European Union

Debbie Rabina

Scott Johnston

McPherson Library, University of Victoria, Victoria, British Columbia, Canada

Abstract

This entry provides an overview of European Union (EU) information policy, focusing on its formation, its goals, and its influence. European Union information policy refers to the legislation and strategies pertaining to the European policy for the creation of the information society. It is concerned with economic and industrial competitiveness, with an emphasis on the role that information and communication technologies play in revolutionizing everyday life, a broad goal with far reaching socioeconomic implications. This discussion, however, will be confined to information policy areas of greatest interest to information professionals, namely copyright and intellectual property, data protection and privacy, e-government and digitization.

INTRODUCTION

European Union (EU) information policy refers to the legislation and strategies pertaining to the European policy for the creation of information society. This includes areas such as copyright and intellectual property, data protection and privacy, e-government and digitization. It is also concerned with economic and industrial competitiveness with an emphasis on the role that information and communication technologies play in revolutionizing everyday life. Information policy is viewed as contributing to the larger goals and objectives of the EU itself, particularly in relation to the European economy.

The beginning of a comprehensive information policy for the EU can be traced back to 1994 when the European Council, recognizing the profound effect that global information and communication systems were having on European society, began to establish a foundation for an information and communication infrastructure. At the root of the EU information policy was an effort to build a legal and physical infrastructure designed to promote a global information society.

Following a brief discussion of the key concepts in information policy, we will provide a brief history of the EU, before going on to discuss the formation, legislation, and implementation of information policy in the EU as they pertain to library and information science. Lastly we will discuss some of the major issues facing information policy in the EU and the influence it has had in the United States and on an international stage.

BACKGROUND

Information Policy

Information policy is an umbrella term for official government policies that govern the collection, storage, and dissemination of official information within a specific jurisdiction. Weingarten describes information policy as a set of all public laws, regulations, and policies that encourage, discourage, or regulate the creation, use, storage, and communication of information.^[1]

Information policy is a socially constructed concept and should be evaluated in relation to the environment in which it is practiced. The term “information policy” connotes a U.S. perspective and is not the preferred term of the EU. EU policy makers have adopted the term “Information Society” to denote a broader set of issues relating to aspects of information management.

While only one perspective can be presented and developed here, it is important that readers be made aware of alternative views. Keeping in mind the likely readership of the *Encyclopedia of Library and Information Science* and attempting to offer a unified perspective of information policy as expressed in the information policy entry, this entry examines EU information policy in a narrowly defined way that is analogous to the discussion of information policy as generally perceived in the United States.

We limit our discussion to the EU information policy as defined by Hernon and Relyea in the third edition of *ELIS* and diverge from it when expansion in the framework is necessary for understanding the EU landscape.

For purposes of this entry, we have chosen to adopt the definition used by Hernon and Relyea: “Information policy is [...] a set of interrelated principles, laws, guidelines, rules, regulations, and procedures guiding the oversight and management of the information *life cycle*: the production, collection, distribution/dissemination, retrieval and use, and retirement, including preservation, of information.”^[2]

At the government level, information policy is designed to be operational and is executed by a series of laws, regulations, and court cases that reflect a country’s approach to information policy. Cahill and Overman argue that information policy is value-based and that these values are normative in nature and specific to the value system of individual countries.^[3] Normative ethics attempt to balance right and wrong behaviors as they are perceived through the underlying morals and arrive at the correct moral principles by which all people should be morally guided.^[4]

A research perspective of information policy takes into account various theories that explain and justify information policies. Theoretical frameworks are important to the discussion of information policy in that they provide justification for the policies enacted, serve as the underlying imprint of policies and situate them in a specific time and place. With regard to information policies, legal jurisdictions such as federal governments, as in the United States, or supragovernmental organizations, as in the EU, design and enact policies. Such policies are intended to help resolve inherent problems in information technology and provide pragmatic models for resolving concrete problems. The wide penetration of information technologies highlighted the conflict between policy values, such as information privacy or information ownership, and unconfined use of technology. While there are numerous theoretical approaches to information policy, some of the more widespread approaches include ethical frameworks and economic frameworks.

Many ethical approaches to information policy are based on John Stuart Mill’s essay on Utilitarianism, published originally in 1859.^[5] Recognizing that absolute ethics are not possible to achieve, Mill promotes pragmatic ethics which results in the greatest good for the greatest number of people affected. A utilitarian approach will result in different policies from an approach based on basic human rights. For example, in the United States many of the areas associated with information policy are based on basic rights of the people as articulated in the U.S. Constitution. In Europe, where a Millsian pragmatic ethics approach is more common, information policy is seen to be serving greater considerations than just those of the citizenry.^[6]

Another theoretical framework for understanding information policy in the European context is to understand it as a series of policies that support economic growth. Researchers who advocate this approach contend that

thriving economies depend on uniform laws and regulations of information among and between governments. Such researchers include Samuelson and Varian^[7] and Reidenberg.^[8] While the scope of this entry does not allow us to delve deep into theoretical frameworks, the utilitarian and economic perspectives contribute to a better understanding of the approach to information policy that directs the EU.

Historical Overview of the European Union

The EU is a supranational body working towards peace and prosperity in Europe. The EU maintains a unique structure. It is not a federation of countries, but rather an organization in which each member state maintains its own independent governments and legislatures, while at the same time agreeing to have common institutions with the power to make decisions on matters of joint interest to other member states.

The origins of the EU can be traced back to 1950 when French Foreign Minister Robert Schuman conceived the idea of European integration. Europe Day is celebrated on May 9 to mark the anniversary (Europa http://europa.eu/abc/symbols/9-may/euday_en.htm).

As of June 2008, there were 27 member states as well as three candidate countries (Turkey, Croatia, and Macedonia) awaiting membership. Many of the most recent countries to join the EU in 2004 were members of the former Soviet bloc and include the Czech Republic, Cyprus, Estonia, Hungary, Latvia, Lithuania, Malta, Poland, Slovakia, and Slovenia. In 2007 Bulgaria and Romania also met the democratic and economic threshold requirements for joining the EU and became member states. They joined the earlier members, comprising Belgium, France, Germany, Italy, Luxembourg, the Netherlands (1957), Denmark, Ireland, United Kingdom (1973), Greece (1981), Portugal, Spain (1986), Austria, Finland, and Sweden (1995). Switzerland and Norway elected not to join the EU in order to preserve their neutrality.

The total population of the EU is nearly half a billion people. It covers an area of 1.67 M sq mi, making it nearly twice as large as the United States in terms of population, and slightly under half its size in area. The EU has no constitution. Attempts to ratify one failed in 2004 when France, followed by the Netherlands, voted against a proposed constitution. The prospect of a unifying constitution has become even more remote with the Irish vote against it in June 2008.

The EU functions on the basis of four founding treaties that, in the absence of a constitution, provide the rationale and justification of all decision-making for the Union. Thus, legislation is always directly linked to specific articles in the founding treaties. The four treaties that form the basis of the EU are *The treaty establishing the European Coal and Steel community, 1951* (commonly referred to as *The Treaty of Paris*); *The treaty establishing the European*

economic community, 1957 (The Treaty of Rome); *The treaty establishing the European Atomic Energy Community, 1957* (EURATOM); and the *Treaty on European Union, 1992* (Treaty of Maastricht). Treaties are referred to as Primary Law and are regarded as constitutional in statutes. All other legislation is defined as secondary and based on the treaties. Legislation in the EU is binding to all member nations, citizens living within its borders, and companies that conduct business with the EU.^[9]

As the main initiator of legislation within the EU, the European Commission is instrumental in the policy-making process regarding the information society. While the Council and the Parliament pass legislation, they can only act on proposals from the Commission. The Commission, the most powerful of the EU institutions, acts as the executive branch of the EU and is the guardian of EU treaties; as such it is entrusted with the role of initiating legislation stemming from treaties (The European Commission at a glance).^[10] The Commission is divided into 26 Directorate-Generals (which are similar to government ministries) overseeing different subject areas. Information policy falls under the domain of the Information Society and Media Directorate-General (DG Infso).

European Union government policy is divided into three “pillars.” The first pillar covers policy relating to the three communities of the European Coal and Steel Community, the Economic Community, and EURATOM (European Atomic Energy Community). The second pillar covers common foreign and security policy (CFSP). The third pillar covers justice and home affairs, judicial cooperation in civil and criminal matters, police cooperation, and immigration policy. With few exceptions, policies and legislation relating to information policy fall under the first pillar.

INFORMATION POLICY IN THE EUROPEAN UNION

History

The European Commission’s role in the EU is to prepare and implement legislation adopted by the European Council and the European Parliament in connection with EU policies acting as the EU’s executive branch. It was not until 1979 that the European Commission became involved in information policy when it issued a report that “addressed the role of networks in economic competition and the necessity of cooperation for developing new networks and services.”^[11] Not only does information policy in the EU lack the long tradition it has in the United States, the term *information policy* itself is not in frequent use in the European context, the preferred term being *information society* (Europa glossary).^[12]

Attempts to address legal and regulatory issues relating to the information society did not begin in earnest until the

1990s, with the publication of the Bangemann report, discussed below.^[13]

Objectives

The brief definition provided by the Europa glossary of the term *information society* places emphasis on information and communication technologies and their potential role in revolutionizing everyday life, and in this respect is more similar to the Clinton administration’s use of the term *National Information Infrastructure*.^[14] The information society is therefore a technologically driven phenomenon and, not surprisingly, many of the efforts of the EU are devoted to developing policies centering on technological issues, specifically policies relating to market regulation, introduction of new technologies, and benefiting from information and communications technologies (Europe’s Information Society: Information Society Policies).^[15]

Commission report (94) 347 situates the role and vision of the information society as a force for economic growth: “*The information society is on its way. A ‘digital revolution’ is triggering structural changes comparable to last century’s industrial revolution with the corresponding high economic stakes. The process cannot be stopped and will lead eventually to a knowledge-based economy*” (COM (94) 347).^[16]

Challenges

The EU, for reasons both historical and pragmatic, focuses more efforts on execution than on vision. While its institutions are democratic, and increased transparency continues to be one of the EU’s main goals, it is not in the purest sense a democratic institution since the EU’s Parliament, whose members are elected directly by the citizens of the member states, has limited ability to exercise control over the European Commission. Transparency and access to information continue to be a challenge in spite of the adoption of a code of conduct regulating access to EU information.^[17]

EUROPEAN INFORMATION SOCIETY

Unlike the United States, where information policy is piecemeal and for the most part reactive, information policy in the EU is preemptive. The EU views information policy as contributing to its larger goals and objectives, and considers it an important part of the European economy.

The 1994 Bangemann report is often identified as the foundation of information policy for the EU. It resulted from the European Council’s request for a report outlining measures and steps to be considered when laying a foundation for an information and communication

infrastructure. The report recognized the profound effect that global information and communication systems were having on European society, including economic and social life.

The report lays out a vision for a European information society and recommends actions to achieve desired outcomes, but devotes little attention to a thorough analysis of the existing preconditions in Europe. Subsequent reports, particularly by the European Commission Blankert et al.,^[18] followed the Bangemann report and advised the Commission on a recommended course of action. The Bangemann report was therefore advisory in nature, while implementation was left to EU executives.

At the root of the EU's information policy is an effort to build a legal and physical infrastructure that will promote a global information society. The European Council's vision is for the goal to be achieved by a combination of free market forces and support from the regulatory system (Bangemann report, 4) that will address the needs of all EU citizens in an equitable way and prevent a digital divide (Bangemann report, 7). The goal is for everyone to benefit from the opportunities offered by technology while controlling its adverse effects. To curb the adverse effects of an information-based society, the Bangemann report recommended emphasis be placed on education and training. Free market forces play a major role in achieving the goals of an information society, and the Bangemann report calls for ending monopolies of telecommunication operators and the system of political burdens that are inherent in them (chap. 2). The action plan of the report perceives the role of government as safeguarding competitive forces (chap. 2).

The report set out 10 areas related to ICT in which Europe needs to strengthen itself in order to compete in the global economy. These areas, included in chapter four of the report, are described as applications, or building blocks, of the information society. They include: teleworking, distance learning, a network for universities and research centers, telematic services for small- and medium-sized enterprises, road traffic management, air traffic control, health care networks, electronic tendering; trans-European public administration networks; city information highways.

To promote the goals of the information society, in 1999 the European Commission launched the eEurope initiative to accelerate Europe's entry into the digital age. The result was eEurope 2002, which sought to create a cheaper, faster, and more secure Internet, to invest in people and skills, and to stimulate the use of the Internet throughout the EU (EU Guide to the Digital Economy, 2003).^[19] eEurope 2002 was followed by eEurope 2005, and most recently i2010 (Europe's Information Society).^[20] i2010 is "an initiative which will provide an integrated approach to information society and audiovisual policies in the EU, covering regulation, research, and deployment and promoting cultural diversity." i2010 aims

to achieve through regulation, funding, and partnerships, a single European information space for competitive society and media services, and is currently the main coordinating body for European information society initiatives and implementation in the EU. i2010 actions are directed toward establishing a single European space for affordable and secure ICT both in terms of diverse content and digital services. Other objectives of i2010 are in developing private-public sector partnerships that promote technological innovation and providing an inclusive framework for ICT public services, particularly in the area of e-governments.

Within the framework of the EU, responsibility for the information society was initially that of the Commissioner for Enterprise and Information Society, but as roles expanded, so did the office, which is now known as the Commissioner for Enterprise and Industry (Enterprise and Industry).^[21]

MAJOR ISSUES

Several important directives are included under the umbrella of Information Society legislation. These are conveniently collected and updated on the EU's Web site and updated regularly (Europa. Activities on the EU).^[22] The main areas of activity most relevant to information professionals include ICT, Intellectual Property, Electronic Commerce, and Data Protection and Privacy.

Information and Communications Technologies (ICT)

The EU's information policy approach is closely linked with communication policy in general and ICT in particular. Both are perceived as equal contributors to the information society. Information and communication are valued as commodities designed for both high-end markets as well as mass consumption.

The Commission of the European Communities set about implementing the recommendation of the Bangemann report, and the initial recommendations for implementation was articulated in an action plan (COM (94) 347). The action plan reiterates the conclusions of the Bangemann report, emphasizing the role of the private sector in infrastructure development, and of the member states in creating a stable regulatory framework. In addition, the action plan proposes a response in four areas: ICT regulatory framework, intellectual property rights, privacy, and electronic protection.

The current legislative framework relating to information policy has attached information policy areas to a "Telecoms Package" that regulates electronic communications in the public sector. The Telecoms Package includes a directive on data protection,^[23] the general framework,^[24] access and interconnection,^[25] authorization and licensing,^[26] and universal access.^[27]

The objective of the Telecom Package is to provide a regulatory framework for electronic communication that opens the telecommunication markets to competition. This emerged from the recognition that enabling technologies are converging and that a single horizontal framework is therefore required to support them. The framework addresses regulation harmonization in areas of fixed-line voice telephony, mobile and broadband communications, and cable and satellite television.

The most recent assessment found that significant progress has been made in achieving that goal and that the focus should now be on management of the radio spectrum and the streamlining of market reviews (COM(2006) 334 final).^[28] In addition, since revenue growth in the area of electronic communication has outperformed growth in the overall EU economy, the framework is considered a success (COM(2006) 334 final).

The preemptive nature of EU information policy is in evidence in many of the general frameworks such as the regulatory framework for electronic communication outlined above. As in other areas of the information society that draft policy based on predictions of the long-term developments in the area (COM (2005) 229 final), the electronic communication framework also attempts to anticipate future developments in the area. Specifically, the report predicts that four major technological developments will occur by 2016: 1) a migration to “all Internet Protocol (information policy)” networks; 2) increased use of wireless communications and wireless platforms; 3) deployment of fiber-optic connections in the local access networks; and 4) the transition to digital television (COM (2006) 334 final).

Intellectual Property

One of the first official reports to address intellectual property was the 1988 Green Paper (COM (88) 172).^[29] It was followed by a Commission Working Programme (COM (90) 584).^[30] The most recent version, and currently in effect, is Directive 2001/29/EC^[31] on the harmonization of certain aspects of copyright and related rights in the information society, which passed in May 22, 2001. The Directive puts the EU in compliance with the World Intellectual Property Organization (WIPO) Copyright Treaty.

The Directive, which went into effect on December 22, 2002, is a slim document, consisting of 15 articles described in 10 pages, and outlines the EU approach to copyright in the broadest terms, leaving many details to individual member nations.

The purpose of the Directive, as described in the preamble, is primarily to contribute to the economic strength of the EU within the framework of the EU’s mandate to establish an information society. While the Directive is most commonly regarded as legislation regulating copyright, some of the related rights mentioned in the law’s subtitle are significant to the EU’s policy framework and

include freedom and expression (Directive 2001/29/EC preamble sections 1–3).

Although the underlying notion of intellectual property protection as an incentive for creativity lies outside of the scope of the Directive, the document clearly assumes that copyright and other intellectual property are economic engines for growth. Section 4 of the preamble states that the desired outcome of the Directive is increased competitiveness in ICT as well as across industrial sectors. This, it is argued, will in turn encourage new job creation (Directive 2001/29/EC preamble section 4). An additional goal of the Directive is to be in compliance with the WIPO (Directive 2001/29/EC preamble section 15).

The main articles of the Directive address reproduction rights, distribution rights, technological protection, and digital rights management. Fair Use, known in the Directive as “Exceptions to Copyright,” is addressed in article 6^[41]. The Directive takes a strict stand on avoiding technological protections, banning not only circumvention of access control technologies which regulate access to information and protected content, but also copy control technologies which prevent additional reproductions beyond the first sale of a copyrighted work (Directive 2001/29/EC Article 6). This is a departure from the Digital Millennium Copyright Act (DMCA)^[32] that only made access circumvention illegal. The Directive is interpreted as more favorable to users than the DMCA in that it tilts the balance in favor of the user.^[33]

Moral rights (commonly referred to as “droit d’auteur”), which include the right of authors to have their work properly attributed, to preserve the integrity of their work, and to publish anonymously or under a pseudonym, are outside the scope of the Copyright Directive. Section 19 of the preface leaves the exercise and implementation of moral rights to individual member states to work out the issues in accordance with the Berne Convention and the WIPO Copyright treaty.

Electronic Commerce

Within the framework of the EU, electronic commerce (e-Commerce) is viewed as an integral part of the information society structure in that it is an essential part of the network environment. The Directive on Electronic Commerce^[34] addresses electronic commerce, defamation, misleading advertising, and infringement of trademarks. The Directive sets rules and supports regulations for transparency for online service providers, and electronic contracts, and limits the liability of intermediary service providers. In addition to e-Commerce as a means of increasing for profit business transactions, it is also the basis for eGovernment services within the EU. The EU policy in the field of eGovernment is part of the previously mentioned i2010 plan (COM (2005) 229 final)^[35] and has five objectives all intended to increase services to citizens. eGovernment encourages the use of ICT in the public

sector and public administration to improve service, increase democratic participation, and encourage transparency. Areas directly affected by eGovernment initiatives are research and development and scientific, technical, and medical (STM) publishing. The eGovernment action plan (COM (2006) 173 final)^[36] outlines the steps to be taken during 2006–2010 to achieve eGovernment goals.

Data Protection and Privacy

Privacy in the context of the EU is closely linked with data protection. While in the United States the term “privacy” prevails, the legislation that regulates matters relating to privacy in the EU primarily covers the protection of personal data. The EU’s concern with data protection is mainly to allow data exchange between member states in a manner that ensures a high level of protection within the EU, as well as guaranteeing citizens the same high level of security when exporting data outside the EU. Thus the main legislation protecting privacy, Directive 95/46/EC,^[37] prohibits the transfer of personal data of or about EU citizens held in registered databases, to non-EU countries that do not meet the adequacy standard for data protection. The 1995 Directive went into effect in 1998, and subsequent legislation includes the Directive on privacy and electronic communications (Directive 2002/58/EC), an amendment to the 2002 directive,^[38] as well as additional legislation and regulation (for complete list see http://ec.europa.eu/justice_home/fsj/privacy/law/index_en.htm).^[39]

In order for U.S. companies to trade database information with the EU, the U.S. Department of Commerce established the Safe Harbor framework, a voluntary system of participation approved in 2000. This framework allows participating American companies to trade information with EU companies (Export gov).^[40] The EU has addressed data transfer with the United States in two main areas: air passenger data transfer and safe harbor agreements. Data transfer between the EU and the United States is regulation not by legislation (directive) but by a series of agreements and letters issued by the EU (Commission decisions of Third Countries).^[41] These documents allow the transfer of information about EU citizens to the United States for purposes of travel and commerce, with the condition that the United States will afford EU citizens data the same level of protection awarded to them by the EU directives. While some of these decisions are unilateral and take the form of statements issued by the EU, there also include joint agreements between the EU and the United States that enable travel and commerce.

A recent example of the impact of EU legislation can be seen in the opinion of the Article 29 Working Group.^[42] It determined that search engine companies, in order to comply with the EU Data Protection Directive, must “delete or irreversibly anonymise personal data” once collection goals have been met. The opinion states

that this requirement applies to search engine companies based outside Europe as well as those in Europe, since European privacy laws apply to search engines (Article 29).

In the aftermath of 9/11, privacy protection and violation has changed dramatically in the United States, particularly as a result of the USA PATRIOT Act. The effect in Europe has not been as pronounced. The difference in perspective is the result of Europe’s historical experience with terrorism: many European countries were victims of international and internal terrorism prior to the September 11, 2001 attack on the United States such as the Irish Republican Army in England, Bader Meinhof in Germany, and the Red Brigade in Italy. The EU has always viewed terrorism on a domestic level to be handled by each country’s own criminal code: criminal law is part of “Justice and Home Affairs” as described in the Third Pillar of the Treaty on the EU. While this approach remained unchanged following the September 11 attacks, the EU did address questions of terrorism in June 2002 with a Decision on Combating Terrorism (2002/475/JHA),^[43] which defines terrorist groups and acts with regard to groups, individuals, and supporters and calls on member states to align their legislation so that the uniform definitions apply in all member states.

While human rights were not addressed in the EU’s Decision, the Council of Europe did address the matter in its 2002 Guidelines on Human Rights and the Fight against Terrorism (Council of Europe, 2002).^[44] The Council of Europe is not part of the EU per se, although they are considered an affiliated organization operating under the flag of the EU and working toward European integration (Council of Europe, 2008).^[45] The Guidelines guarantee respect for human rights in the fight against terrorism declaring that states “may not use indiscriminate measures which would only undermine the fundamental values they seek to protect,” and prohibiting the use of torture in all circumstances. Sections V and VI of the Guidelines specifically address privacy, including privacy with respect to collection of personal data, searches of body, houses and personal effects, surveillance, and wire tapping. While such actions are permitted as measures to fight terrorism and protect citizens, the Guidelines state that they should be exercised with the utmost caution, only when no other measures exist, and should be employed in accordance with provision of domestic laws. In addition, such actions may be subject for external review and open to challenges before a court of law.

Other Activities of Europe’s Information Society

In addition to the areas outlined above, the EU is engaged in other activities to further the development of an information society. These include promoting digital infrastructure, encouraging research and innovation, and promoting a safer Internet. (Europe’s Information Society:

information society activities).^[46] The safer Internet activities address illegal and harmful content on the Internet and resulted from a green paper issued by the Commission in 1996 (Commission of the European Union COM(96) 487 final)^[47] and include a 4-year program that addresses four main issues: fighting against illegal content, tackling unwanted and harmful content, promoting a safer environment, and awareness-raising. More recent activity in the area also includes a recommendation to member states regarding protection of minors and human dignity in online activities.^[48] While U.S. case law has supported the view that the Internet is private space and therefore not directed by government action, the EU is more heavily involved in content regulation.

IMPLICATIONS

Information and communication technology, and more specifically the Internet, are making national borders more difficult to manage or control from specific jurisdictions. This trend has been occurring and gradually increasing as Internet activity grows, and is driven by two very different approaches to information on both sides of the Atlantic. The U.S. government does not regulate cyberspace and is concerned only by harmful use of information, while the EU protects its citizens from the wrongful collection of information.

In the United States, this is a *de facto* phenomenon, resulting from market forces that set standards and establish benchmarks for information flow and trade driven by private enterprises for financial benefit. In the EU the *de facto* eradication of international borders is recognized but not allowed free reign. Rather is it curtailed by *de jure* legislation and regulation by the EU that in effect imposes European standards of information trade on non-EU countries. This has compelled the U.S. government to diverge from its *laissez faire* policy and negotiate the Safe Harbor Agreement that enables information exchange between the United States and the EU. Concerns that the Internet will undermine the authority of governments have not materialized. In the case of the EU, the opposite has occurred. The EU's approach to transborder information flow has resulted in imposing these standards and practices on countries wanting to trade with the EU.

CONCLUSION

European Union information policy refers to the legislation and strategies pertaining to the European policy for the creation of information society. The goal of this entry was to provide an overview of the unique and influential nature of the EU's approach to information policy by discussing its formation, goals, and ultimately its influence. In the broadest sense, EU information policy is

concerned with economic and industrial competitiveness with an emphasis on the role that information technologies play in revolutionizing everyday life, a broad goal with far reaching socioeconomic implications. Our discussion has focused on several policy areas of greatest interest to information professionals by discussing the approach that the EU has taken addressing areas such as copyright, intellectual property, data protection and privacy, and e-government. In its aim to bring EU information to its citizens, EU information policy has challenged policy notions by establishing new levels of cooperation between major state institutions and all information and communication matters.

GLOSSARY

Directive: Legislation, which is binding to EU member nations.

Green paper: Documents published by the European Commission. Their purpose is to stimulate discussion and may eventually lead to legislation, but their recommendations are not binding. Green papers are often followed by White papers.

Information society: synonymous with "new information and communication technologies" (ICT).

Pillars of the EU: Three pillars form the basic structure of the EU, and are: 1) the Community pillar, corresponding to the three Communities: the European Community, the European Atomic Energy Community, and the former European Coal and Steel Community; 2) the common foreign and security policy, and 3) the policy and judicial cooperation in criminal pillar.

White paper: Documents published by the European Commission that contain proposals for actions in a specific area. When White papers are received favorably they lead to actions in the area they address.

Information Policy: United States

Peter Hernon

Graduate School of Library and Information Science, Simmons College, Boston, Massachusetts, U.S.A.

Harold C. Relyea

Congressional Research Service, Library of Congress, Washington, District of Columbia, U.S.A.

Abstract

Information policy, a field encompassing both public policy and information science, treats information as both a commodity—adheres to the economic theory of property rights—and a resource to be collected, protected, shared, manipulated, and managed. Although the literature often refers to information policy in the singular, there is no single all-encompassing policy. Rather, information *policies* tend to address specific issues and, at times, to be fragmented, overlapping, and contradictory.

INTRODUCTION

Information is “essential to our existence” and assumes a “life of its own.”^[1] Information policy then is a set of interrelated principles, laws, guidelines, rules, regulations, and procedures guiding the oversight and management of the information *life cycle*: the production, collection, distribution/dissemination, retrieval and use, and retirement, including preservation, of information. Information policy also embraces access to, and use of, information and records; records relate to the conduct of government business and provide an audit trail for holding government accountable. Collectively, policies form a framework that “profoundly affects the manner in which an individual in a society, indeed a society itself, makes political, economic, and social choices.”^[2]

Much of the discussion of U.S. information policy revolves around actions taken or planned by government, either at the national or subnational levels. Since the mid-1990s, commercial transactions on the Internet—called electronic commerce—have grown substantially. At the same time, governments at various levels within the United States have embraced electronic government (e-government or e-gov). At the federal level, for instance, e-government focuses on the political economy of the nation, and relevant information policies concentrate on issues related to Internet infrastructure, resource management, and the provision of online services and resources. Clearly, the Internet, and its World Wide Web, have become the primary channels for the federal government’s dissemination of resources to the public; that public is now global and extends to people of all ages (from youth to the elderly). Still, the private and not-for-profit sectors play a legitimate and important role in the provision of

government information to specific constituency groups and to the public at large.

Information policy has global implications, but it also occurs outside of government. It takes place within and among organizations, associations, and other groups. This introductory essay cannot touch on all aspects of information policy and still provide a semblance of unity. For this reason, the essay does not address censorship, telecommunications, the press, broadcasting, First Amendment issues, propaganda, intellectual property rights, patents and trademarks, and archival management. Moreover, the essay focuses on American national government information policy. It discusses some key policy areas and stakeholders, shows how policy is formulated, and identifies issues central to an understanding of information policy in the twenty-first century. There is no single corpus of statutory or administrative law to coordinate information policies of federal agencies and to eliminate ambiguities in federal information policies. Some policies pertain to an agency and specific activities; others apply to a branch of government, have governmentwide application, or have international ramifications. Nonetheless, a group of core policies pertain to the management of government information resources and the information life cycle. For an overview of these policies, see Hernon.^[3]

SIGNIFICANCE OF INFORMATION POLICY TO THE LIBRARY COMMUNITY

Government policies provide a framework within which libraries and information centers must function. These policies often determine what types of publications will be issued, the availability of government funds, and how funds will be allocated and spent. They may relate directly

to the management of libraries and the types of services provided and address issues such as Internet privacy and security. Obviously, librarians must understand the policy arena and how it affects the services they provide, as well as how to influence the policy-making process, as they try to have their perspective addressed during policy development.

Another reason why librarians should be knowledgeable about information policy is that libraries and information centers are part of a larger organization (e.g., city government, an academic institution, or a corporation). The internal policies set by that organization impact on libraries and information centers and set the constraints under which they function. Moreover, external policies also have an impact on the ability of libraries and information centers to meet stated goals and objectives.

Perhaps two examples of the importance of information policy might be beneficial. First, as part of its Library Awareness Program, during the 1970s and part of the 1980s, the Federal Bureau of Investigation (FBI) visited libraries, tried to solicit information about library users, and compiled investigative records on library personnel. A full understanding of the program and the options open to the library community necessitates knowledge of the Department of Justice's counterintelligence activities and the grounds on which the FBI justified its actions.^[4] Any rebuttal of the FBI's justification for its policies that might result in a change of agency policy and practices must address the legal basis on which the FBI justified its actions. To effect change, librarians need extensive knowledge of policy terminology (e.g., the differences among executive orders, circulars, and directives), how policy is formulated, and strategies that might result in policy modification or reversal.

Following the terrorist attacks of September 11, the U.S. Geological Survey requested the Government Printing Office (GPO) to instruct those depository libraries that received a CD-ROM on the characteristics of large surface-water supplies in the United States to destroy their copies. The GPO ordered the libraries to comply and destroy the CD-ROM immediately. "Subsequently, the Federal Bureau of Investigation visited several Federal Depository Libraries to determine whether that order had been carried out. This occurred without consultation with the GPO or the Geological Survey. . . ."^[5] In a memorandum, dated March 13, 2002, attorney Thomas Susman of Ropes and Gray observed:

The delicate balance between responding to concerns relating to homeland security while ensuring public access to government information presents new challenges to many libraries. What limitations, if any, should be on access to selected government information resources? Are there criteria to consider as to whether information resources should be publicly available? Similarly, many libraries that participate in the Federal Depository Library

Program . . . are concerned that changes may be forthcoming in the information access and dissemination policies of federal agencies.^[5]

In formulating their response, depository libraries should ask, "What does the law say?" If they are dissatisfied with the answer, they might inquire about "How feasible is it to change the law?" "What support might we gather from other stakeholders?" "Are there any changes in the law under consideration?" "What is the likelihood of those changes being enacted?" and "Can you influence the shaping of those changes?" Clearly, libraries participating in the depository program need to understand their legal responsibilities, as well as those of GPO, as specified in Chapter 19 of Title 44 of the *United States Code*.

HISTORICAL DEVELOPMENT OF INFORMATION POLICY

Information policy existed in America long before the establishment of the federal government in 1789. Indeed, it probably can be said that information policy began with the arrival of the first European colonists who brought with them the information policies of their homeland. The common law rights of Englishmen were particularly important in this regard and were directly influential in the development of the American legal system well into the early nineteenth century.^[6]

The experience of the colonists differed regarding patterns of communication and information dissemination.^[7] Consequently, their expectations about the availability and accessibility of government information varied from one region to the next. Eventually, however, as England became the predominant power in the Atlantic territories, conflicts over information and "the rights of Englishmen" came to be commonly experienced throughout the American colonies. Disputes arose over the secret activities of royal governors and colonial legislatures, the public accessibility of official records, and proper respect for personal privacy.^[8-10] These and other perceived violations of individual rights by George III kindled the fires of revolt and the rebellion that resulted in American independence.

Within the new nation, information policy was given primary expression in the Articles of Confederation and state constitutions, the latter containing expressions of fundamental rights guaranteeing freedom of the press and personal privacy. These documents would later be important sources for James Madison when drafting the Bill of Rights for the U.S. Constitution. Very little historical research, however, has been conducted on the development of information policy during the American colonial and confederation eras. Some general histories of government institutions and practices of the period provide occasional bits of pertinent knowledge, but much work remains to be done before a better understanding of information

policy prior to the establishment of the federal government can be realized.^[11–13]

The history of federal information policy development begins with the Philadelphia convention of 1787, which, itself, owing to the secrecy in which it occurred, was a special information policy event.^[14] The Constitution of the United States created a limited government with some explicit powers and responsibilities. Certain of these concerned information matters. Among the enumerated powers of Congress, for example, are authority to “establish Post Offices and post Roads,” to “promote the Progress of Science and useful Arts, by securing for limited Times to Authors and Inventors the exclusive Right to their respective Writings and Discoveries,” and “make Rules for the Government and Regulation of the land and naval Forces” (Article I, Section 8, clauses 7, 8, and 14), and to “make all needful Rules and Regulations respecting the Territory or other Property belonging to the United States” (Article IV, Section 3, clause 2).

In the Bill of Rights, which was subsequently appended to the Constitution, guarantees are made concerning speech and press freedoms (Amendment I), the security of personal papers against “unreasonable searches and seizures” (Amendment IV), and not being “compelled in any Criminal Case to be a witness against” oneself (Amendment V). Also included are rights to a public trial in criminal prosecution and “to be informed of the nature and cause of the accusation; to be confronted with the witnesses against [oneself]; [and] to have [a] compulsory process for obtaining witnesses in [one’s] favor” (Amendment VI).

The Constitution created a government accountable to the people and itself, as well. There was an expectation that government leaders would keep the citizenry informed of developments, or at least maintain a record of their activities. In this regard, the Constitution specifies that each House of Congress “shall keep a Journal of its Proceedings, and from time to time publish the same, excepting such Parts as may in their Judgement require Secrecy” (Article I, Section 5, clause 3). Concerning the duties of electors, the Twelfth Amendment prescribes that “they shall make distinct lists of all persons voted for as President, and of all persons voted for as Vice-President, and the number of votes for each, which lists they shall sign and certify” (Article II, Section 1, clause 3). With regard to the subnational level of government, the Constitution states: “Full Faith and Credit shall be given in each State to the Public Acts, Records, and judicial Proceedings of every other State” (Article IV, Section 1, clause 1).

Moreover, with its system of checks and balances, the Constitution anticipated that each branch would be knowledgeable of the activities and interests of the other two. In this regard, the Constitution specifically provides that, when the President vetoes a bill, “he shall return it, with his Objections to that House in which it shall have originated, who shall enter the Objections at large

on their Journal; and proceed to reconsider it” (Article I, Section 7, clause 2). Concerning interbranch accountability, provision is made for the President to “require the Opinion, in writing, of the principal Officer in each of the executive Departments, upon any Subject relating to the Duties of their respective Offices” (Article II, Section 2, clause 1). The Constitution also indicates that the President “shall from time to time give to the Congress Information of the State of the Union, and recommend to their Consideration such Measures as he shall judge necessary and expedient” (Article II, Section 3). Finally, as a consequence of the separation of powers doctrine of the Constitution, presidents determined, early in the life of the federal government, that a discretion might be exercised regarding requests for information from the other branches. For example, President Washington contemplated discretion in 1792 and exercised it four years later, the first invocation of what would subsequently be called “executive privilege” or the privilege of the Chief Executive to withhold requested information from Congress or the Judiciary for institutional reasons.^[11,15–22] Congress has claimed and exercised similar powers.^[23–25]

In many regards, these constitutional references to information matters indicate some fundamental expectations regarding government accountability and communication, the exercise of certain popular rights regarding information, and subsequent legislation on at least a few particular information subjects. Furthermore, historically, as experience and practice suggested that Congress create and refine additional statutory information policies, these, among other constitutional considerations, have guided the legislative and oversight processes.

An information policy area that quickly commanded the attention of the new federal government and continued to be refined throughout the nineteenth century was official publication. The matter had been debated during the Constitutional Convention of 1787. James Wilson of Pennsylvania, addressing a proposal to allow each chamber of the Federal Congress a discretion as to the parts of their journal that would be published, told the delegates: “These people have the right to know what their Agents are doing or have done, and it should not be in the option of the Legislature to conceal their proceedings.”^[26] The following year, during the Virginia Convention on the new Constitution, James Madison and George Mason raised a similar consideration when speaking about the importance of publishing all receipts and expenditures of public money under the new government.^[27]

In deference to views such as these, the federal Congress quickly provided for the printing and distribution of both laws and treaties,^[28–35] the preservation of state paper,^[36] and the maintenance of official files in the new departments.^[28,29,37] In 1813, the printing and distribution of both the Senate and House journals was authorized.^[38] Congressional floor debate was variously reported in the *Register of Debates*, *Congressional Globe*, and, beginning

in 1873, the *Congressional Record*. See the statutes^[39,40] and McPherson^[41] and of related interest, see Childs.^[42,43]

Provision was initially made in 1846 for the routine printing of all congressional reports, special documents (which included Executive Branch materials), and bills.^[44] Although these responsibilities were met for many years through the use of contract printers, such arrangements proved to be subject to considerable political abuse. Consequently, in 1860, Congress established GPO to produce all of its literature and to serve, as well, the printing needs of the Executive Branch.^[45] Additional aspects of governmentwide printing and publication policy were set with the Printing Act of 1895, which is the source of much of the basic policy still found in the printing chapters of Title 44 of the *United States Code*.^[46,47]

Congress, in addition to providing for publication of the statutes and a variety of legislative literature (and executive materials produced as Senate or House documents), promoting newspaper reprinting of the laws and treaties,^[48] and circulating printed documents through official sources, also developed a depository library program to further facilitate public knowledge of government actions. In 1859, the Secretary of the Interior was statutorily tasked with distributing all books printed or purchased for the use of the federal government, except those for the particular use of Congress or Executive Branch entities.^[49] A decade later, a subordinate officer in the Department—the Superintendent of Public Documents—was mandated to perform this responsibility.^[50] Distributions were made to certain libraries throughout the country that were designated to be depositories for government publications. This arrangement had been begun in 1813 with regard to congressional materials^[38] and extended in 1857 to include other federal literature.^[51] The Printing Act of 1895 relocated the Superintendent of Public Documents within GPO.^[52–54]

In the relocation process, the superintendent was also given responsibility for managing the sale of documents and preparing periodic indices of GPO products. Until 1904, the sales stock available to the superintendent derived entirely from such materials as were provided for this purpose by the departments and agencies or were returned from depository libraries. The situation was altered when the superintendent was granted authority to reprint any departmental publication, with the consent of the pertinent secretary, for public sale.^[55] Congress legislated comparable discretion to reproduce its documents in 1922.^[56]

Shortly after the dawn of the twentieth century, the federal government entered a new phase—the rise of the administrative state. Among the forces contributing to this development was the Progressive Movement, which sought greater government intervention into, and regulation of, various sectors of American society. With the United States' entry into World War I, regulatory activities further expanded and the number of administrative

agencies so involved increased. In the postwar era, government expansion momentarily slowed but began again with the onset of the Great Depression and the arrival of the New Deal.

As federal regulatory powers and administrative entities dramatically grew during this period, there was a concomitant increase in both the number and variety of controlling directives, regulations, and requirements. Soon, problems of accountability, uniformity in the form and promulgation of agency directives, and public access to agency administrative records arose. To address the first of these issues, an Executive Branch gazette was created—the *Federal Register*—in July 1935.^[57] Two years later came the *Code of Federal Regulations*. This cumulation of the authorities appearing in the gazette contained almost all operative agency regulations and was eventually updated annually.^[58] Later, the general statutory authority underlying the *Federal Register* was relied on for the creation of other series of publications, namely, the *United States Government Manual* (1939–), the *Public Papers of the President* (1960–), and the *Weekly Compilation of Presidential Documents* (1965–).

The efforts of a study committee established by the Attorney General^[59] contributed to the legislating of the Administrative Procedure Act of 1946,^[60] which brought uniformity to the form and promulgation of agency regulations. The statute also contained an important public information section that directed the agencies to publish in the *Federal Register* “the established places at which, and methods whereby, the public may secure information or make submittals or requests.”^[61] However, broad discretionary allowances also were made for protecting information, and a changing climate of opinion within the federal bureaucracy soon transformed this public information mandate into a basis for administrative secrecy. Elements of the press community gave particular attention to the unwillingness of federal agencies, as well as some other government entities, to disclose requested information.^[62–66] In 1955, a special subcommittee on government information was established in the House of Representatives; it inaugurated, with assistance from elements of the press, a major probe of agency information access policy and practice.^[67]

Subsequently, in 1966, after a long congressional examination and a difficult legislative struggle, the public information section of the Administrative Procedure Act was replaced by a new statute and a new concept in information access. The Freedom of Information (FOI) Act established a presumptive right of public access to department and agency records, specified nine categories of information that could be exempted from the rule of disclosure, and provided for court resolution of disputes over the availability of requested materials.^[68] Later amended in 1974, 1976, 1986, and 1996, with portions subject to considerable judicial interpretation, the statute has

remained a very effective tool for enabling public access to topical records of the administrative state. It has also served as a model for other information access laws, such as the Privacy Act of 1974,^[69] and open government statutes, such as the Federal Advisory Committee Act of 1972^[70] and the Government in the Sunshine Act of 1976.^[71]

With the end of World War II and the onset of the Cold War, the federal government entered still another new phase—the rise of the national security state. From the outset of the era until the mid-1960s, it was a time of strong, unilateral leadership by the president in the external affairs of the country and was marked by the creation of new agencies and policies to safeguard the nation. Several such innovations were taken regarding information policy.^[72,75] These developments, however, built on a few prior policy actions. Since the earliest days of the Republic, for example, government officials had engaged in the practice of assigning a secret status to certain kinds of sensitive information, usually concerning foreign affairs, defense, or intelligence matters. The Executive Branch, including the armed forces, engaged in such information security–secrecy practices for over a half century before they were given direct statutory authorization.^[76] Formal military secrecy directives or regulations appeared only after the Civil War. The initial Army General Order of 1869 concerning security–secrecy pertained to the physical protection of forts and coastal defenses. Such facilities were not to be photographed or otherwise depicted without prior permission from appropriate officials. This limited application underwent a series of evolutionary adjustments and, shortly after the United States' entry into World War I, resulted in a fully developed information security classification system.^[77] In 1911 and 1917, Congress provided for the criminal punishment of espionage and the acquisition of valuable defense information by spies.^[78–80] Neither law, however, specifically sanctioned the information secrecy practices of the military departments or the armed forces. Initially, the military departments made no mention of the espionage laws in their information security orders and directives, but soon such regulations began referring to these laws as a possible basis for their enforcement.

Relying on a 1938 statute concerning the protection of armed forces installations and equipment and “information relative thereto,” President Franklin D. Roosevelt assumed responsibility for security classification policy and procedures by issuing an executive order setting such policy. It largely paralleled Army and Navy regulations for marking and handling secret records and gave civilian employees of the military departments authority to classify information. However, the legislative history of the 1938 statute, on which the president relied to issue his directive, provided no indication that Congress anticipated or expected that such a security classification arrangement would be created.^[81] Nevertheless, it was the beginning of

presidential leadership in setting security classification policy.

Congress seemingly has evidenced a general reluctance to authorize directly or legislate a governmentwide information security classification system. Although it has mandated information security arrangements for special areas such as atomic energy,^[82] intelligence,^[83] or patent applications having national security implications,^[84,85] Congress, through various committees and subcommittees, for 30 years, successfully encouraged and pressured presidents from Eisenhower to Reagan to narrow classification criteria and limit discretionary authority to classify.^[77] The Reagan administration's sweeping 1982 executive order reversed the prior historical trend by expanding the categories of classifiable information, by mandating that information falling within these categories be classified, by making reclassification authority available, by admonishing classifiers to favor classification in deciding close cases, and by eliminating automatic declassification arrangements.^[86]

Furthermore, with the realization of the national security state at the end of World War II and the onset of the Cold War and the penchant for secrecy, publication of the law of the land became impaired not by circumstances of accident or inadequate means, but, instead, as a consequence of concealment by design. The National Security Act of 1947^[87] sought to preserve and perpetuate the nation *by any and all means*. In 1951, President Harry S. Truman signed an executive order giving almost every government agency broad discretionary authority to classify information “in order to protect the security of the United States.”^[88] The following year, a still secret presidential directive created the National Security Agency. Not officially acknowledged to exist until 1957, it remains one of the most reticent components of the national security leviathan.^[89]

The heart of the national security state, if for no other reason than its membership, is the National Security Council (NSC). After a modest beginning under President Truman, it gained importance during the Eisenhower administration, waned somewhat during the Kennedy administration, but regained its importance and has remained highly influential ever since. The written policy pronouncements of the president emanating from the NSC increasingly appear to have oftentimes assumed the character of secret law.

Shortly after its creation, the NSC began to produce four types of policy papers: basic comprehensive policy statements on a broad variety of national security problems, together with pertinent political, economic, and military pursuit strategies; situation profiles of large geographic areas or specific countries; assessments of mobilization, arms control, atomic energy, and other functional matters; and organizational statements on the council, foreign intelligence, and internal security structure and activities. The initial products in the series apparently

were of the geographic type; the first comprehensive policy statement was completed and given NSC approval in November 1948.^[89]

Subsequent presidents have attached different names to the NSC secret papers. For example, Jimmy Carter issued secret Presidential Directives, Ronald Reagan changed the name to National Security Decision Directives, and George H.W. Bush referred to them as National Security Directives. Under William Clinton, they became Presidential Decision Directives, and George W. Bush nominated them as National Security Presidential Directives. (See Hernon, Relyea et al.,^[3] Chap. 6 for a discussion of the national security state and the various forms in which a president communicates public policy.)

Now, most of the NSC directives produced up to 1960 have been declassified and are accessible at the relevant presidential libraries, whereas most of those produced in subsequent years remain classified, “and details about them are largely unavailable for congressional or public scrutiny.”^[89] In summary, as the General Accounting Office has pointed out, unlike executive orders, these directives “embody foreign and military policy-making guidance rather than specific instructions; are classified; are usually directed only to NSC and the most senior executive branch officials; and do not appear to be issued under statutory authority conferred by Congress...”^[90] However, these directives embody policy-making guidance, but some of them have provided specific instruction. For example, Presidential Decision Directive 63, issued by President Carter, dealt with the fight against cyberterrorism. Among the tasks it recommended were the development of a plan to improve intelligence gathering and an expansion of international cooperation.

Finally, apart from national security secrecy considerations, information is also lawfully protected to maintain the integrity of persons. In the case of individuals, such protection is understood as privacy. However, in the case of corporate persons, protection extends to proprietary or commercially valuable information.

Individual privacy, the wish not to be intruded on, probably predates recorded history. Certainly it is one of the presocietal or “natural rights” that the founding fathers sought to preserve.^[91] When drafting the Bill of Rights, they gave constitutional recognition to privacy expectations in the First, Third, Fourth, Fifth, and Ninth Amendments, which the Supreme Court characterized as comprising a penumbral right of privacy in a landmark 1965 decision.^[92,93]

Through the years, for various governmental activities and programs involving the collection and maintenance of personally identifiable information, such as the census and income tax returns, prohibitions have been legislated on the disclosure of such data. These statutory restrictions are recognized in the FOI Act,^[94] and the Privacy Act prohibits federal agencies from collecting some kinds of personally identifiable information.^[95] The Privacy Act also

allows American citizens to gain access to, and make supplementary corrections of, a great many agency records on themselves. Examples of laws that have been enacted to provide citizens with greater control over personal records held by third parties include the Fair Credit Reporting Act,^[96] the Privacy Act, the Family Educational Rights and Privacy (or “Buckley”) Act,^[97] and the Pupils’ Rights Act.^[98]

Furthermore, more than a century ago, the Supreme Court recognized corporations as being a “person,” but it has not vested them with the privacy rights reserved for individuals.^[99] Generally, when legal protection has been accorded to the information of corporate entities, it has been done for economic reasons and without explanation in terms of privacy rights. Perhaps the best-known statutory prohibition in this regard is the Trade Secrets Act, which makes the disclosure of trade secrets by a federal officer or employee criminally punishable.^[100] A 1977 study prepared by the Department of Justice identified 90 operative statutes “reflecting varied approaches to the regulation of the disclosure by federal agencies of the information they collect from or maintain about business entities.”^[101] Moreover, open government laws, such as the FOI Act and the Government in the Sunshine Act, contain exemptions for the protection of trade secrets and confidential commercial information.

A number of issues affect the continued growth of the Internet for personal, government, and business purposes. Among these, for instance, are Internet privacy, computer security, access to broadband (high-speed) services, e-commerce, commercial Web site adherence to “fair information practices” proposed by the Federal Trade Commission, the receipt of unsolicited commercial electronic mail (spam or junk e-mail), and government information technology management. The practices include: 1) providing notice to users of their information practices before collecting personal information, 2) allowing the public choice about whether and how personal information is used, 3) allowing users access to data collected and the ability to content its accuracy, and 4) ensuring security of the information from unauthorized use. A critical question relates to whether or not industry can regulate itself, or if legislation is required for the protection of consumer privacy. The Internet makes it easier for the public and private sectors to obtain information about consumers and possibly use that information to the consumers’ detriment. That issue focuses on the extent to which webmasters gather personally identifiable information about individuals and share that information with third parties, perhaps without the knowledge or consent of the people concerned.

In the wake of the September 11 terrorist attacks, the issue of law enforcement monitoring of Internet and web activity has become more controversial, with some advocating that law enforcement receive additional tools to combat terrorism, whereas others are concerned about the

intrusion on civil liberties. The USA PATRIOT Act (P.L. 107-56) grants law enforcement officials additional authority to monitor Internet activity. Some of the provisions of Title II of that law expand the scope of subpoenas for records of electronic communications to include records commonly associated with Internet usage (e.g., session times and duration); allow Internet Service Providers to divulge records or other information (but not the contents of communications) pertaining to a subscriber if they believe there is immediate danger of death or serious physical injury, or as otherwise authorized, and requires them to divulge such records or information (excluding the contents of communications) to a government entity under certain conditions; and add routing and addressing information (used in Internet communications) that a government agency may capture by using pen registers and trap-and-trace devices as authorized by court order, while excluding the content of any wire or electronic communications.

ELECTRONIC GOVERNMENT

Electronic government is an evolving concept that currently includes four important areas: 1) the delivery of services (government-to-citizen); 2) providing information to the public; 3) facilitating the procurement of goods and services (government-to-business and business-to-government); and 4) facilitating efficient exchanges within and between agencies (government-to-government). FirstGov (<http://www.firstgov.gov/>) is a portal that facilitates access to digital resources relevant to each of these areas. Regarding the provision of information, it provides access to information at the national and subnational levels and provides a link to FedStats (<http://www.fedstats.gov/>), which enables users to gain access to statistical information from more than 100 government agencies. For some agencies, a service includes the provision of e-mail reference service; the information seeker will receive a response to his or her query.

Subordinate to the four current areas of electronic government is a fifth area, namely, the government as an on-line retailer. At their Web sites, government bodies (e.g., the Department of Treasury, the U.S. Mint, Amtrak, the General Services Administration, the U.S. Postal Service, the U.S. Geological Survey, the National Park Service, and GPO) conduct on-line sales.^[102]

E-government and the various information policy instruments expand the five areas into 11 purposes:^[103]

- Communication between an agency and the public, and communication among government bodies.
 - Information access and meeting the information needs of the American public, from the nation's youth to senior citizens.
 - Service delivery and the provision of online services, including online sales.
 - Procurement or the purchase of services and goods from the private sector.
 - Security, including the protection of Internet transactions among government entities and between those entities and the public against obstruction, diversion, interception, and falsification. Security also extends to protection against hacking of home pages and safeguarding Web sites and computers against viruses. Furthermore, security pertains to the storage of electronic information to assure its integrity and prevent unauthorized disclosure.
 - Privacy of personally identifiable information and unauthorized use of cookies that can be attached to computers so that agencies can monitor the public's use of their Web sites.
 - Management of e-government operations and related matters.
 - Maintenance of information technology systems that underlie e-government.
 - Digital divide and reducing the perceived disparity that results from portions of the population not having the ability to use information technology due to a lack of access, skill, or both. This is why government agencies use standard plug-ins that the public can freely download from the Web, or agencies provide free access to plug-ins that they specially created for some of their products.
 - Emergency response, or dealing with a sudden crisis that threatens the nation. For example, following September 11, the public used government Web sites to monitor the situation and report alleged terrorist sightings to the appropriate agency. Special institutions, such as the Federal Emergency Management Agency (FEMA), have been created to respond to, coordinate the efforts of other agencies to respond to, and plan for national emergencies. Such institutions have coordinated and contributed to the preparation and maintenance of emergency plans, such as the Federal Response Plan for the delivery of federal disaster assistance, and standby directives, such as Executive Order 12656 of November 18, 1988, assigning emergency preparedness responsibilities among the federal departments and agencies. In addition, Congress has enacted various laws that provide the president ready authority to address an emergency, as well as some standby statutory powers that may be selectively activated under the terms of the National Emergencies Act of 1976, as amended.
 - Oversight of the development of e-government by both the Executive Branch and Congress.
- A central issue for policy makers is the development of a comprehensive, but flexible, strategy to coordinate the disparate e-government initiatives across the federal

government. In 2001, the Bush administration proposed the concept of plug-and-play e-government, called component-based architecture (CBA), whereby some agencies develop basic components that others can use. In March, the Office of Management and Budget (OMB) released CBA models for 24 cross-agency e-government initiatives, which “will help agencies decide what technology they need to complete their e-government projects and will also help agencies work better together.”^[104]

As William Clinton prepared to leave the presidency, the National Archives and Records Administration (NARA) revealed that it had treated the White House Web site as a record and had captured images of it every 2 years of his 8-year tenure as president. The various government bodies from the three branches offer millions of pages on their Web sites, and over the years, they have posted an extensive amount of information on these pages. Once the material is removed, most likely, it may not be regarded as a record and reviewed by NARA for possible retention. Nonetheless, federal agencies generate a “torrent of electronic records,” and this tendency “has overwhelmed the ability of “NARA to identify, review and determine which ones merit retention, and preserve them.”^[105]

THE LITERATURE ON INFORMATION POLICY

The Appendix of the *United States Government Information: Policies and Sources*^[31] identifies source material (finding aids, monographs, government reports, and Web sites) that covers information policy from the perspective of different disciplines and stakeholders. Some of the better-known sources for keeping abreast of the latest developments include the following:

- *Federal Computer Week.*
- *Government Computer News.*
- *Government Information Quarterly.*
- *Privacy Times.*

The CD-ROM accompanying *United States Government Information* reprints historically significant works on information policy and contains, as well, exercises and self-help guides.

SOME POLICY ISSUES

Overview

Since the publication of the Porat study in 1977,^[106] little progress has been made in further developing detailed typologies of policy issues, using sophisticated methods to organize and relate issues or producing better methods of clarifying issues and their interrelationships. Many

policy issues are part of both a larger and smaller issue, and resolution of one issue often depends on resolution of another.

The typologies characterize government information policy prior to the emergence of the Internet and electronic government. For example, Hernon and McClure, who analyzed a wide range of policy issues, underscored that:^[107]

- The published policy literature is repetitive in the broad themes it addresses.
- Surprisingly, little duplication exists among specific policy issues; each issue tends to emphasize specific and unique aspects of the broader themes.
- The literature devotes little attention to issues related to the role of libraries in the provision of government information and the information needs and gathering behaviors of user segments.
- Policy issues can be isolated in their impact on other policy issues.

Public Access to Government Information

As Hernon and McClure noted, “government information is a broad term that encompasses both published and unpublished information that . . . government either does or does not intend to make public.”^[107] Public information encompasses that which a government department or agency chooses to make available on its own or the courts force it to release. In contrast, private information is intended solely for internal use within government. There is a gray area between public (released) and private (protected) information. The availability of information in the gray area would be determined through the FOI Act, the Privacy Act, judicial review, and such. Clearly, the definition of key terms should be an important component of information policy.

E-government and the various information policies behind it have altered the landscape of public access. The government releases more types of information resources electronically than it did in the past, and FirstGov represents an attempt to create a portal that provides subject access to information resources across the three branches of the federal government. Although far from providing comprehensive access, it does serve as a tool for those unfamiliar with the structure and organizational complexity of the government. Beyond such a portal, the search process becomes more complex, and there are guides to navigating both the electronic and print environments. At the same time, although there is no governmentwide recommendation as to which types of viewers government entities should follow and different entities may use different ones,^[108] the government relies on those viewers that the public can download free of charge through the Web. The government has also created specialized software that might have operated in a mainframe

environment but has been modified to function in an e-government environment. Thus, the public can download these software packages at an agency's home page and run the application through a personal computer. Examples of such applications include:^[108]

- GEODE (GEO-DATA Explorer; U.S. Geological Survey (USGS); <http://dssl.er.usgs.gov/>), a tool for accessing, viewing, and downloading "information from geospatial databases containing a broad spectrum of data produced by the USGS and other government agencies."
- BASINS (Better Assessment Science Integrating Point and Nonpoint Sources; Environmental Protection Agency's (EPA) Office of Science and Technology; <http://www.epa.gov/epahome/gis.htm>) "integrates a geographic information system (GIS), national watershed data, and state-of-the-art environmental assessment and modeling tools into one convenient package."
- EXTRACT (U.S. Bureau of the Census; <http://www.census.gov/epcd/www/extract.html>), "a general purpose data display and extension tool that works with bureau files recorded in dBase format."
- Map-It (U.S. Geological Survey; <http://stellwagen.er.usgs.gov/mapit/>), a map generator that "takes longitude/latitude pairs as input and plots them on a Mercator projection map along with land/sea and political boundaries."

Another means of informing the public is webcasting, which is an audiovisual presentation, such as a lecture, training session or program, or news conference that can be viewed online in real time or archived for later viewing. The Department of Housing and Urban Development, for instance, provides live webcasts of training and public events (<http://www.hud.gov/webcasts/index.cfm>), and congressional committees often offer live hearings through webcasting. Most government Web sites recommend RealPlayer from RealNetworks, Inc. (Seattle, WA; <http://www.real.com/>) to view and hear webcasts.

EPA's Maps on Demand EnviroMapper (<http://maps.epa.gov/enviromapper/>) provides users with interactive GIS functionality using some of the agency's spatial data for the conterminous United States. The USGS's National Atlas Online (<http://www-atlas.usgs.gov/atlasvue.html>), which uses Macromedia's Shockwave (<http://sdc.shockwave.com/shockwave/download/>), allows users to customize maps interactively with a user's Web browser. Finally, EPA's "Dumptown Game" (<http://www.epa.gov/recyclecity/gameintro.htm>) also uses Shockwave, but, in this instance, as a browser viewer to watch the images move and change as users interact with the program as the City Manager of Recycle City. The "Dumptown Game" is one of more than 100 government Web sites aimed at the nation's youth.^[108]

Federal agencies are cognizant that their web visitors use a variety of workstation platforms (Intel and Apple), browsers (Netscape and Microsoft Internet Explorer), Internet access speeds [telephone, cable, and Digital Subscriber Line (DSL) modems in addition to local area networks], and workstation-installed software productivity applications (e.g., Microsoft and Corel office suites). As a result, government Web sites are making efforts to meet individual user needs by providing the public with alternative choices for viewing information and downloading files based on the speed of their Internet connection and installed viewer. An excellent example is the Video Gallery of the National Aeronautics and Space Administration (NASA) (<http://www.nasa.gov/gallery/video/index.html>), which provides users with choices of movie format based on file size (large and small versions), desired viewer (the same movie in either Quicktime or RealPlayer format), and movie resolution (which affects file size) based on the speed of the user's connection to the Internet (high resolution for larger files and for cable modems and T1 users, medium resolution and average file sizes for fast dial-up modem users, and low resolutions with smaller file sizes for slower dial-up users).^[108]

The on-line "help and customization" services that some government Web sites provide include fully functional advanced search engines with Boolean and document search options, perhaps tailored to the educational level of the information seeker (e.g., Department of Education, <http://www.ed.gov/search/advSearchForm.jsp>); excellent help pages (e.g., THOMAS of the Library of Congress, <http://thomas.loc.gov/tfaqs/tfaq15/pdfhelp.html>) and online guides (e.g., for installing GEODE, <http://dssl.er.usgs.gov/help/>); the establishment of personalized web pages, whereby the public collects their favorite information from the site and receives updates on a regular basis (the user logs onto the site using a password) (e.g., "My TradeNet," <http://tradenet.gov/>); and the free and convenient access to full-text and bibliographic records of the Department of Energy, such as research and development reports in the sciences and some other disciplines, using a persistent uniform resource locator (PURL) (see "DOE Information Bridge," <http://www.osti.gov/bridge/>).^[108]

An example of private and public sector cooperation involves mapping products that government agencies prepare. These products might be linked to a commercially available GIS that combines mapping and a data set and that permits users to display multiple data items. A GIS is a computerized system that captures, stores, manipulates, analyzes, and presents data coded to a particular location or area on the Earth's surface (latitude and longitude). Federal agencies use GISs for resource management, planning, resource allocation, and the setting of and compliance with regulations. More precisely, they use the computerized systems for land use analysis and planning, natural resource management, land cover interpretation,

demographic mapping and analysis, transportation route or traffic corridor selection, natural hazard assessment, global research, military reconnaissance, etc.^[109]

Depository Library Programs

The Government Printing Office administers the best-known depository program, in which more than 1300 libraries receive publications that GPO receives and distributes for public use. A key question is: “What is the role of this depository program (as well as other ones) in the environment of e-government that has been briefly sketched in this essay?” Is it more than being a resource for lessening the digital divide (see below) providing access to historical documents, and assisting the public in navigating the government’s presence on the Web and furnishing the necessary plug-ins to retrieval needed government information resources? Depository libraries can provide the public with free access to fee-based statistical compilations of the Department of Commerce’s STAT-USA.

Complicating matters, the only study to document the number of users of the depository program (actually only academic and public depositories) recorded 167,000 of them for a typical week in the latter 1980s.^[110] In contrast, during a typically week, the Bureau of the Census, for instance, has more than 1 million “hits” on its home page. Thus, under e-government, government departments and agencies can directly, efficiently, and effectively provide the public with both information and services, without having to rely on third parties such as depository libraries. Perhaps the major exception to this generalization is the depository program of the Patent and Trademark Office, where anyone seeking patent or trademark information can rely on the special knowledge and search skills of the highly trained staff at these libraries. Seeking information on patent and trademarks can constitute a complex search process, and even the agency’s home page acknowledges the program and encourages information seekers to use the resources under the direction of depository library staff.

Policy Framework

At the federal level of government, information policy may be developed in a variety of ways and prescribed in a number of different forms. The prescribed way for Congress to establish information policy is largely through the constitutionally specified legislative process. A member of Congress formally introduces a proposal in the form of a bill or a joint resolution. Usually the measure is one endorsed by the member, but legislation can be offered “by request” on behalf of the president. Ideally, the proposal is referred to the appropriate committee of jurisdiction; given a hearing, where public comment is received; marked up in accordance with committee wishes; reported to the floor; and voted on by the chamber membership. After the other house of Congress completes similar action

on the measure or one nearly like it, a conference committee may be necessary to resolve differences in the two adopted versions. After both houses have agreed to the single compromise bill, the proposal is presented to the president for signature. When signed into law, the measure attains the status of being a statute and, usually, is positioned within the *United States Code*. If the president vetoes it, Congress has an opportunity to override and, if successful, the measure becomes a statute.^[3]

There are, however, other techniques and procedures available to Congress for setting policy. Within its own domain, the two houses of Congress adopt rules and standards that constitute policy. In 1980, for example, the Senate adopted a simple resolution that changed the rules of that body to increase public access to its archived records.^[111,112] A similar reform was instituted in the House of Representatives in 1989 with the adoption of a simple resolution amending the rules of the House for the 101st Congress.^[113,114] Committees of the House and Senate set rules for themselves that constitute information policy. For example, many committees have a rule on how they handle and maintain security classified or other sensitive information.

Congress also appropriates funds for the departments and agencies. This fiscal authority can be directly and indirectly used to set policy. A verbal understanding or committee report language concerning the operation and/or expansion of a program in question may accompany a generous appropriation for an information program. Similarly, funds may be denied or withheld for a program. Moreover, a permanent prohibition may be instituted through the appropriation process.^[115]

Finally, policy may be set through informal but, nonetheless, documented agreements. A powerful committee chairman may ask an agency head to conduct some information operation in a particular way; the verbal agreement, extracted at a hearing, is captured in the transcript of the proceeding. In the same regard, an exchange of letters may be used to set policy. For example, shortly after President Kennedy assumed office, the chairman of the House Special Subcommittee on Government Information wrote to him asking for an explanation of how his administration would invoke “executive privilege.” By return letter, Kennedy pledged he would exclusively exercise this power and would assume personal responsibility for its use. Sometimes, of course, a record documenting an informal agreement setting policy may be difficult, if not impossible, to locate. Furthermore, sometimes no such record exists.

The federal courts also make information policy. When a judicial decision is rendered on a dispute, it may uphold the status quo or modify an existing policy at issue. Moreover, in writing an opinion on a decision, a judge or judges may offer views or prescribe a procedure that assumes a policy character. For example, law professor Robert Vaughn’s FOI Act lawsuit to gain access to Civil Service Commission evaluations of certain agencies’ personnel

management programs and other similar reports prepared by the Bureau of Personnel Management resulted not only in a ruling in his favor but also inaugurated agency creation of an index that would enable courts to facilitate reference to particular portions of documents and to know the exact exemption being relied on by the government for each controverted section of a document at issue. Such an index allows a requester to prepare better arguments for the disclosure of sought records. An agency must identify specific portions of disputed documents that are being exempted from disclosure and must justify in detail the reasons for protecting particular information under certain exemptions.^[116] The FOI Act, in particular, has been subject to a considerable amount of such judicial gloss.

Courts and individual judges also enjoy a considerable amount of authority for setting information policy for their domains. Federal court rules, practices, and procedures, not inconsistent with legislative enactments, have the force and effect of statutes, but any such rule inconsistent with a statute is inoperative. The Supreme Court promulgates rules for itself and the separate lower federal courts.^[117] These are for the general guidance of the courts. However, because the individual Courts of Appeals in their circuits and federal District Courts throughout the country encounter special local conditions and circumstances, they are empowered to make their own special rules, not inconsistent with the rules of general applications set down for them by the Supreme Court.^[118] Furthermore, within all of these rules, presiding trial judges have some latitude to control information (e.g., issue a protective order, seal documents, or perhaps close a portion of a proceedings). Such actions may be viewed as policy making; their significance will vary depending on their public effect.

Judicial opinions, once filed, are publicly available at least in typescript at the courthouse of the authoring judge (s). Some judges, however, may be slow to file their prepared views. Commercial publishing firms obtain these opinions and produce various compilations, including the well-known *Federal Reporter* and *Federal Supplement* series. Supreme Court opinions, while also available in commercially published form, are produced by GPO in the *United States Reports* series.

Within the Executive Branch, information policy may be prescribed through a wide variety of forms emanating from the Oval Office, an agency fulfilling a governmentwide responsibility, or an agency serving only its own personnel. In the first category, the president may set policy through the issuance of a directive, such as an executive order or a national security decision directive, a letter, a memorandum, or simply an announcement. In almost all cases, such policy making cannot conflict with statutory expressions and is of an administrative nature and internal to the government. Occasionally, however, the president may exercise some constitutional authority (e.g., Commander in Chief powers) resulting in policy

expression in conflict with congressionally legislated policy. For example, some speculate that one of the reasons why Congress has not directly legislated information security classification policy, except in very specific program areas, is that the president has the prerogative in this field by virtue of being constitutionally Chief Executive and Commander in Chief. Conflicts between a congressional and a presidential policy expression are sometimes settled by the courts but are oftentimes left to political settlement.

Governmentwide policy on a matter may be set by a particular agency. For many years, OMB, and the Bureau of the Budget before it, has issued circulars, announcements, and guidelines on a variety of fiscal and administrative matters. The Privacy Act of 1974 authorized OMB to issue governmentwide guidance and regulations for implementing the statute.^[119]

Finally, each agency produces forms of policy. Again, the expectation is that these agency expressions of policy will not conflict with statutes or other superior policy forms, such as a presidential directive or governmentwide guidance. Agencies issue regulations implementing and interpreting statutes and presidential policy instruments, internal administrative orders and directives governing their organization and operation, and staff manuals, such as security classification guidebooks, all of which contain expressions of policy. Most agency regulations can be found in the *Code of Federal Regulations*. Draft and new regulations, as well as some other agency orders and directives, are published, when first issued, in the *Federal Register*. Nonetheless, some of this material is unpublished and fugitive; however, it might appear on an agency's home page.

Stakeholders Affecting Information Policy

Given the impact of information policies on many facets of one's work and nonwork situations, a listing of stakeholders involved in policy formulation and review would be endless and unproductive. Most professional organizations have a body for presenting their response to draft and newly reported information policies of concern to their membership; those bodies may also try to shape those policies. For example, they might be invited to present their position at a congressional hearing or to interact with committee staff in shaping initial legislation. It is important that different stakeholders be willing to work with each other and, when necessary, to compromise. Clearly, information policy is subject to the political process. As well, policy makers will be sensitive to the costs of any proposed recommendations and will not react well to calls for creating a new government agency or program. There are, as well, competing priorities such as, of late, homeland security matters, including the creation of a new cabinet-level department charged with such responsibilities.

TOWARD NATIONAL INFORMATION POLICY

In July 1976, the Domestic Council within the Executive Office of the President submitted a report, *National Information Policy*, to President Gerald Ford. The principal recommendation was that “the United States set as a goal the development of a coordinated National Information Policy . . . that is comprehensive, sufficiently sensitive to new technology, and responsive to the implications of the Information Age.”^[120] The report advocated a unified approach to information policy coordinated in the Office of the President.

Subsequent discussions of information policy have encouraged the development of a “requisite arterial system” for “the free and equitable flow of all nonproprietary, nonconfidential information to each individual, regardless of location, level of comprehension, economic status, or other circumstances.”^[121] Such discussions focus on national information policy, but for either government or nongovernment information. Rarely has such policy been viewed as a marriage of all information resources, whether they are government or nongovernment.

Trying to develop national information policy, the National Commission on Libraries and Information Science, the British Library, and the Canadian Institute for Research on Policy formulated the Glenierin Declaration, a trilateral statement that could serve as a preamble for national, or international, information policy that recognizes the impact of information on national economies and societies. Although dated, that declaration articulates an agenda of issues, initiatives, and strategies for achieving the marriage of all information resources.^[122]

Briefly, national information policy conveys a sense of national purpose and represents guiding principles leading to the integration of all publicly available government information in the United States, regardless of the level of government producing that information. Moreover, that integration combines government and nongovernment information, extends bibliographic control over that information, and produces mechanisms for gaining effective and efficient access to that information. In contrast, federal information policy has the force of law and variously binds the federal government to prescribed courses of action.

One purpose of national information policy is to improve the dissemination of government information and to bring pertinent government information resources produced in the United States to the resolution of various information needs of the citizenry. Of course, national information policy might have another component: the identification of significant foreign source material that, e.g., will lead to a U.S.-based patent or scientific breakthrough. National information policy should encourage differentiation between quantity and quality of information and discourage the generation of information that merely adds to information overload.

The National Commission on Libraries and Information Science (NCLIS), a proponent of national information policy, has reaffirmed its support of national information policy through its declaration of “Principles of Public Information,” such as with *Principle 1: The public has the right of access to public information*: Government agencies should guarantee open, timely and uninhibited access to public information except where restricted by law. People should be able to access public information, regardless of its format, without any special training or expertise.”^[123]

In 2000, NCLIS asked Robert M. Hayes, Professor Emeritus at the University of California, Los Angeles, and chair of the 1982 NCLIS Public Sector/Private Sector Task Force, to reflect on the task force’s findings, conclusions, and recommendations 20 years later. In his reflection, he discusses seven principles and 27 recommendations.^[124] It is encouraging to note that e-government has met most of the principles and recommendations.

E-government, with its attempt to make government become “citizen-centered,”^[125] is achieving national information policy. E-government is forging partnerships and alliances with the private sector and government agencies (even those at subnational levels of government). As a result, more, better organized, and better displayed, government information is readily available. Furthermore, right on their home pages, they tailor access to information for specialized audiences. For example, the Library of Congress’s home page (<http://www.loc.gov/>) enables information seekers to search by whether they are “researchers,” “law researchers,” “librarians and archivists,” “teachers,” “publishers,” “persons with disabilities,” or “blind persons.”

Government departments and agencies have too much information—not all of which is conducive to Web delivery—to place the entire set on the Web. They might not have organized some of their information resources sufficiently for electronic delivery, and some information may not be conducive to display on the Web. In other instances, agencies may have overlooked some information resources in their possession, thereby letting information resources evade being captured bibliographically and being presented electronically, if deemed of sufficient public interest and value. Naturally, e-government cannot and does not focus on nongovernment information. It would seem that the declarations of policy principles and the private and public sector roles and responsibilities that these principles lay out merit reconsideration in the age of digital government. The conditions stated in these principles no longer exist.

LOOKING TO THE FUTURE

If there is a single dramatic and profound factor of change in information policy at present and for the future, it is the concept of e-government, which recognizes the civic and business role of government in disseminating both

information and services. For a long time, information policy has been viewed and formulated in a context of civil liberties and citizen rights in a democracy. This value will continue to be important but is being joined by the somewhat competing factor of information having economic, global, and national security value, particularly when government information is increasingly available in digital formats that are attractive to information users.

The challenge for the future will be to continue to improve information dissemination through e-government^[126] in balance with post-September 11 security concerns. At the same time, government departments and agencies will need to articulate better how they decide what to include and exclude on their home pages and what happens once information is removed from availability there. Is the information removed to a "library," which is a storehouse that may not be easy to search, "archived," or destroyed?

Most definitely, the amount of information produced annually within the federal government and other levels of government is large and ever-increasing. Although the quantity of information increases, so too does its usefulness to diverse segments of the population. Information policy is crucial to national economic well-being and scientific discovery, as well as maintaining an informed and well-educated citizenry that interacts with the government on a regular basis.

CONCLUSION

The availability of information is no longer restricted by national boundaries. Furthermore, the free market is expanding, and geopolitical structures are undergoing radical changes in the name of e-government. As a result, many policies have broad implications. Local libraries and information centers operate within this broad framework. That framework shapes what information is available, in what forms, at what price, etc. Clearly, libraries can play a part in revitalizing U.S. competitiveness in world markets. However, they have other charges as well. The result is that a host of current and potential policy issues have direct and indirect implications for library and information science as e-government continues to unfold and its infrastructure is developed. It is important that these issues be identified and that the library and information science profession develops strategies that define the role of libraries and information centers in the provision of electronic and print information to the public and that complement the goals of e-government.

Information Practice

Crystal Fulton

Jean Henefer

School of Information and Communication Studies, University College Dublin, Dublin, Ireland

Abstract

The phrase *information practice* is relatively new to the field of Library and Information Science (LIS). Using the works of individuals, such as Foucault, Vygotsky, and Garfinkel, the concept of information practice questions the historical positioning of the individual as the unit of analysis. Instead, information practice proposes that information behavior is best understood by considering information and knowledge constructed as a sociocultural context. Recent LIS scholarship in regions, such as Australia, North America, and the Nordic countries, has drawn upon explorations of discourse to theorize and apply information practice as an umbrella approach to LIS research. This entry explores the concept of information practice and its place among LIS metatheories and application in LIS research.

INTRODUCTION

To commence this entry, a truism is stated: Library and Information Science is a multidisciplinary field. The discipline embraces a multitude of information-related areas concerned with human information behaviors or practices, including information creation, access, retrieval, organization, etc., necessitating the consideration of a range of social science perspectives in the work of practitioners, researchers, and theorists in this field to legitimize and expand research. Equally, because in the social sciences Library and Information Science is relatively new (particularly in terms of empirical theory building compared to other social science disciplines), it is important to embrace new perspectives that draw upon applicable theories and research. However, it is also vital that the discipline does not ignore or negate the fundamental work that has been done by scholars who have explored and may continue to do so, the ways in which human beings engage with information both to build a theoretical basis for this field as well to guide information professionals, including librarians, in their service delivery.

For some decades, the accepted terminology for this particular area of interest and research in the field has been described as *information behavior* (IB).^[1–5] Information behavior researchers and practitioners over the years have dedicated their efforts to exploring and addressing the information needs, information seeking, and information uses of individuals and collectives. All of these endeavors have been undertaken not only to improve information service provision but as well to contribute to theory building in this relatively new field. As embodied by the Association for Information Science and Technology (ASIS&T)’s Special Interest Group: Information Needs, Seeking and Use (SIG USE), the focus of information behavior, encompassing both cognitive and affective behaviors, includes

- Shaping and identifying information needs
- Seeking (and not seeking) information that will address those needs
- Exploring information sources present in one’s context/situation
- Retrieving information from available information sources
- Sharing information with others
- Managing personal information collections
- Communicating and collaborating with others concerning an information need or information resources
- Personal and group-based information use^[6,7]

In recent years, IB has been challenged both as a term and a research approach by a respected body of researchers who have contributed significant work to empirical and IB theory construction.^[8–11] The suggested new nomenclature or “umbrella” term is *information practice*.

This entry includes not only an introduction to information practice, including the philosophical perspectives and the work of the researchers and theorists in this field, but also the recent work being done by individuals who are teasing out this possible “new” term or alternatives to IB for LIS dialog, research, and theory construction from a multidisciplinary perspective.^[12] As well, it will consider other works related to the proposed theoretical basis of information practice and review related current work that seems to place information practices within a wider definition of information behavior in a range of different contexts^[2,4] and discuss new and potentially exciting interpretations.^[2,13,14] Finally, this entry will consider whether there actually is a fundamental difference in perspective between those who describe understanding human activities as information behavior and those who choose information practice, or whether possibly, in reality, this move to an alternative categorization is a semantic

issue. The authors' review of the literature from both perspectives finds that there is mutual agreement that an information activity (or indeed inactivity) is determined by context, whether that be personal, organizational, cultural, etc. Therefore, because LIS research is incorporating the importance of context in studies of information behavior and information practice, the authors will reflect upon the possible need in LIS theory building to move away from focusing on what might be a semantic issue to placing context at the forefront of the development of LIS as a rigorous field in the social sciences.

WHAT IS PRACTICE?

The term *practice* may be defined as pertaining to routine or habitual activities, the idea being to convey a custom or tradition in experience. For example, one definition of practice offered by the *Oxford English Dictionary* is "the habitual doing or carrying on of something; usual, customary, or constant action or performance; conduct," a definition debated by Savolainen and Wilson.^[15] However, the use of the term *practice* in research has yet to be standardized. Some scholars claim to study *practice* as a theoretical construct, while others refer to *practices* as activity-based experience. Similarly, as they attempt to reconstruct their research identities, some scholars refer to their field of specialization as *information seeking practices* and combine this with *information needs*, referring to the long established field of information behavior.^[16] Others have simply appended *information practices* to *information behavior* as an addition to the field of information behavior.^[17] The varying adoptions of the term *practice* to relay disciplinary subject are suggestive of the flux around defining practice as a concept and information practice as a field of study.

Library and Information Science scholars who advocate information practice as a theoretical concept for our field have drawn on Schatzki's^[18] definition of practice. Schatzki explains practice in terms of *human activities*, explaining "Practices are the bundled activities that one type of component of social orders performs."^[18] He summarizes a practice as "a temporally evolving, open-ended set of doings and sayings linked by practical understandings, rules, teleoaffective structure, and general understandings."^[18]

EVOLVING CONCEPTUALIZATIONS OF INFORMATION PRACTICE

In their analysis of LIS metatheories, Talja et al.^[19] state that "A metatheory enables researchers to determine what kind of entities, for example, information, knowledge, users and information retrieval systems are...bringing into researchers' view a specific object of study and a

way of studying this object." The concept of *information practice* arises from the philosophical perspective that because information and knowledge creation is rooted in a sociocultural context, research approaches that concentrate on the individual as the unit of analysis inadequately address the social nature of information processes.

During the late 1970s, constructivism, or the "cognitive viewpoint,"^[20-22] based on educational theories of learning,^[23,24] emerged as a dominant research approach in LIS. Rooted in the view that knowledge is created internally through active, individualized engagement and interpretation of information, constructivism focuses specifically on the individual's sense-making^[25,26] when faced with a gap or uncertainty.^[21] Constructivist researchers^[5,21,27,28] explore the cognitive and affective dimensions of human information behavior and the situational contexts that trigger and may determine the nature and outcome of the individual's engagement with information. Wilson^[29] states that information needs should be included in any model of human information behavior, as well as the drivers that cause the perception of need, those elements that have an effect on response to need, and the nature of the response.

Criticism of the constructivist approach has been raised on a number of levels. Among these is the view that, because the focus is on the individual and his or her internalized construction of mental models or sense-making, the research is, in essence, a study of subjective meanings. Additionally, the "cognitive viewpoint" implicitly creates a perception that LIS is specifically about the effect of information on the individual,^[30] the "information man"^[31] replacing "information" as the core theoretical tenet. Despite the increased attention to information seeking in context (ISIC), constructivist research, it has been argued,^[19,32] does not adequately explore the effect of sociocultural elements on the creation of knowledge nor attributes to language more than an indistinct role as a tool for acquiring evidence of cognitive processes. Methodologically, constructivism has been challenged as well, in terms of the feasibility, either quantitatively or qualitatively, of acquiring an accurate, objective portrait of the inner workings of the human mind engaged in knowledge formation.^[33]

An alternative to constructivism is that of collectivism or social constructivism (reorienting the research approach from the individual to the collective). Based on Vygotsky's^[34] view that knowledge is created through both the individual's internal cognitive processes and their engagement with and experience of a particular sociocultural milieu, collectivism explores the ways in which individuals engage with information and form knowledge through their daily experience of, and participation in, the external, social world. At the center of collectivism is the concept that, because people are social and cultural beings, then it is erroneous to explore their information needs and practices purely from

a psychological perspective. This approach has been explored particularly in domain analysis studies. Hjørland and Albrechtsen^[35] critique the individualistic, cognitive focus of constructivism as being subjective and possibly defective, calling for “investigations of more holistic theories, incorporating knowledge about the cultures in which the information systems are functioning...this implies giving up (or at least supplementing) behavioristic and cognitivist positions in LIS.” Research in this approach has directed its attention away from a unilateral focus on the individual to the information practices inherent in different professions, communities, and environments. Because the empirical work has been conducted predominantly within scholarly discourse communities,^[36–38] there is a concern that collectivism may not have applicability to everyday life information seeking. Wenger’s^[39] theory of communities of practice, with its emphasis on how individuals within a group learn collectively, addresses this issue. Communities of practice exist and can be identified and studied, not only in professional or academic settings, but also in informal, socially based, everyday life settings.

In order to encompass the full dimensions of information seeking and use, social constructionism (or constructionism) is proposed as a potential metatheoretical alternative for LIS. Like collectivism, constructionism is concerned with the social and external use of information, as opposed to the subjective and internal. Knowledge and knowledge structures are not viewed in terms of human beings’ individualized mental states, but rather as social and cultural products and processes. Specifically, the constructionist approach emphasizes language, that is linguistic rather than cognitive processes. It differs from collectivism in that it “entails a more direct focus on rhetorics, argumentation and language use...”^[19]

Information practice has its roots in the work of several theoreticians. At the center of this discussion is philosopher Michel Foucault, whose writings have informed the development of the concept of information practice, as well as the movement to construct an overarching theory of LIS. As Buschman^[40] observes, Foucault “is widely cited, and his insights are adapted in various works that focus on LIS forms of power, discourse, archaeology, silences, exclusion, defining the *other*, domination, and micropractices in the last 15 years of critical-theoretical LIS scholarship.” Foucault^[41] describes discourses as “practices that systematically form the objects of which they speak.” This idea of discourse offers Foucault’s most influential idea adopted in LIS theoretical work.^[40]

This notion of discourse as the object of analysis has long been explored in the academy, with authors, such as Bernd Frohmann^[42,43] and Gary Radford,^[44,45] promoting discourse analysis as a means of understanding the “text” of LIS, including collections, documentary practices, etc. For example, Volosinov’s^[46] work is used to understand discourse by way of classification of discourse through the

selection, organization, and combination of concepts.^[44] In addition to Foucault, proponents of the information practice approach cite other influential figures on thinking about this area, such as Mikhail Bakhtin,^[47] Valentin Volosinov,^[46] Harold Garfinkel,^[48] and Wayne Wiegand.^[49] However, while other philosophers and scholars are linked to Foucault, Foucault remains “far more central to the project at hand.”^[41]

The underlying assumption of the discursive approach is that language holds the key to understanding or establishing meaning in information-related activities, including information needs, seeking, interaction, and sense-making.^[42] Discourse, then, holds a central role in constructing social reality. Information practice research explores “how people give accounts of their information behavior or construct the meanings of technical artifacts in work and everyday life,”^[50] the construction of which Talja and McKenzie assert as significant to “understanding information seeking and technology use from a broader sociological perspective.”^[50] From a theoretical perspective, this reasoning is sound. However, it ignores the fact that discourse, as well as being determined by sociocultural context, is also grounded in cognitive processes. Vygotsky,^[34] while emphasizing the importance of the social context for children’s development, also concentrated his work in exploring the role of inner speech or self-talk as a key to development and sense-making.

INFORMATION PRACTICE IN INFORMATION SCIENCE

Social constructionists generally explain their approach in juxtaposition with the cognitive perspective attributed to information behavior. Savolainen^[11,51] contends that information behavior has been accepted unquestioningly by LIS practitioners, the focus on the individual’s internal processes preventing the exploration of alternative ways of understanding information seeking and use. He asserts that information practice and information behavior are actually “umbrella” discourses. He calls for “a self-reflexive and critical attitude among researchers towards their familiar concepts in order to avoid being ‘trapped’ in their own discursive formations.”^[11]

In proposing an alternative, social constructionists challenge, in a broad sense, the human information behavior approach adopted by LIS researchers. While interest in human beings’ use of information can be traced back to the early decades of the twentieth century, the concept of information behavior is typically perceived to be rooted in the work of researchers, such as William Paisley,^[52] in the 1960s, with Tom Wilson’s^[53] 1981 model of information seeking and use significantly offering an early model that he would later develop to account for human information behavior. By definition, this concept of behavior includes all aspects of the individual’s engagement (or, in some

cases, nonengagement) with information both internally and externally. This approach, while endeavoring to understand the internal processes of individuals, also explores the external factors including “intervening variables”^[54] that help explain the role of information in people’s life worlds. While Wilson is typically cited for establishing information behavior as a theoretical concept for LIS, the models and theories of other prominent LIS scholars, including Paisley,^[52] Bates,^[55] Chatman,^[56,57] Sonnenwald,^[58] Krikelas^[59] (see also Henefer and Fulton^[60]), and Kuhlthau,^[61] form a canon representing a traditional viewpoint under information behavior.^[11] Social constructionists, such as Talja et al.,^[33] argue that while researchers in human information behavior have, over time, expanded their frame of reference and elements of research investigation, the term “behavior,” with its traditional association with internal, cognitive processes, will never provide real understanding, because it is impossible to observe objectively. Of the familiar pioneer names in LIS, Dervin has moved to adopt the term “practice” over “behavior,” placing her in the fold for information practice advocates.^[11]

In proposing the need for critical reflection, Savolainen^[11] argues that, although information practice and information behavior appear to overlap, the two are distinct, emerging from different theoretical perspectives and, therefore, providing differing positions for considering information seeking. Savolainen explores a selection of texts to investigate the development of information practice. In doing so, his analysis takes on a selective text choice, a problematic difficulty already criticized by Buschman^[40] in Foucault’s work. This adopted assumption underlying information practice requires further exploration to support the viability of the approach.

Buschman^[40] examines the potential for a Foucauldian approach in LIS. Importantly, he quotes Habermas’ objections to Foucault’s work, which suggest that Foucault’s logic is flawed, leaving his theory relativist and unable to escape subjectivity. Selectivity of texts and the “death of the subject” are problematic for many of Foucault’s critics, for whom theoretical construct and its language are equally hegemonic. According to Buschman,^[40] “without a theoretical subject or the ability to locate a locus of power, transgression is (literally) meaningless and hopeless, and social and economic relations are frozen—in stasis.” Issues of power remain problematic, where the danger becomes that “the point of LIS discourse analysis becomes LIS discourse analysis.”^[40]

While arguing for an alternative “umbrella” concept, Savolainen^[11] concedes that information behavior and information practice are overlapping at times, such that “researchers may flexibly draw upon alternative metatheoretical ideas in the empirical study of information seeking.” What both perspectives share in common is a belief in context, although implementation may differ. Characterizing context (“the Unruly Beast”) as “a label

for a site of struggle,” Brenda Dervin, in attempting to define what we mean by context in LIS, states that “the only possible conclusion is that there is no term that is more often used, less often defined, and when defined defined so variously as context.”^[62] A critical contribution that constructionism offers to the development of LIS research methodologies lies in its approach to context and how, as researchers, we can examine and refine our empirical studies. Again, those who are exploring the validity of identifying information practice as a more encompassing term to define and investigate the role of information in life worlds make a distinction between their approach to context as compared to that of information behavior researchers.

Constructionists’ approach to context is described as “interpretative,” in that “context is not understood as an independent entity, but as a carrier of meaning.”^[33] In comparison, context, for those studying information behavior, is defined as “objectified.” This implies that information behavior researchers are interested in context in terms of the factors that have an impact on human beings’ use of information, identifying the range of variables that will have an effect on individuals’ needs, seeking, and use, in order to anticipate information behavior in particular situations and best provide systems to facilitate information resolutions. These studies, it is argued, aim to identify the range of variables (internal and external) that either create or affect the actions (or inactions) related to information behavior that have an effect on the object of the research, that is, the individual. Although there is no argument, superficially, with this research approach, constructionists, interested in the applicability of their theory to empirical endeavors, maintain that the crucial dilemma for information behavior researchers is the assumption that this well-established and inadequately challenged methodology does not sufficiently allow for the subjectivity of language and interpretation.

The interpretative approach, proposed by those advocating information practice as an alternative “umbrella” concept, is helpful in terms of providing LIS researchers with a means to experiment with a methodology that challenges the constant critique of the “softness” of social science research. The interpretative approach to context portends that data cannot be interpreted as clear reflections of reality, but that all data collected during the process of research represent not only participants’, but also researchers’ and readers’ sociocultural background assumptions and experiences. Proponents of information practice assert that only through acknowledging that research participants, researchers, and readers bring their own particular sociocultural meanings and interpretations to information seeking and use, can we hope to arrive at a research methodology that will more adequately serve the development of LIS theory. By focusing on the analyses of sociocultural discourses, and simultaneously recognizing and reiterating the subjectivity of all participants’

interpretations (research participant, researcher, and reader), constructionists are advocating a further development in LIS research practices that will contribute to the scientific rigors of our work.

In his consideration of the relevance of a “practice approach” to information science, Cox^[13,14] recognizes that “practice theory” is applicable across a range of disciplines to support theory building. “Communities of Practice” have informed IB research for decades, Ellis^[27] model of academics’ information seeking being an obvious example. In seeking to ground LIS theory building within a robust social science perspective, IP scholars have adopted practice theory as a solution.

In her work placing information literacy within an information practice framework, Lloyd^[63] explores the historical evolution of practice theories, citing the studies of philosophers from Aristotle to Wittgenstein, Bourdieu, and Giddens. She presents the view that practice theories are effective means by which one can study and make sense of “sociality”^[63] (p. 248). In other words, they provide a potentially fruitful framework through which we can explore and build theory about the ways in which human beings engage with information (seeking, gathering, processing, etc.) and critically how the individual’s subsequent construction and use of knowledge is determined by the particular characteristics of the social site they inhabit,^[64] including (but not limited to) cultural norms and expectations, histories, linguistic traditions, economies, and politics. While making an effective argument for conceptualizing information literacy as an information practice, grounded in social sites, Lloyd does concede possible limitations to this approach stating:

At present, however, there is no unified approach or definition of practice, consequently explications of practice differ depending on the ontological and epistemological orientation and interest of the enquirer^[63] (p. 248).

Huizing and Cavanagh^[65] similarly note the lack of a unified practice-based approach. They suggest that practice theory has evolved to contemporary practice-based approaches, with five underlying premises: *including objects*, *stretching interaction*, *foregrounding dynamics*, *explicating knowing*, and *articulating practice*. *Including objects* refers to recognizing the role of material objects in social, organization, and information theories. *Stretching interaction* is about expanding definitions of social interaction to include the influence of human and nonhuman agencies and actions relevant to the interaction. *Foregrounding dynamics* prioritizes actions and practices over actors and organizations in organizing ourselves. *Explicating knowing* offers knowledge as a group, rather than individual, activity. And finally, *articulating practice* refers to the interpretative nature of practice and a contemporary definition of practice.

Bystrom and Lloyd^[12] acknowledge that information practice “lacks fixed meaning in the field of studies.” They offer information practice as a “social practice” that encompasses all human information activities, including producing, seeking, organizing, distributing, and using information. Lloyd^[66] (p. 285), drawing on Schatzki, defines information practice as “an array of information related activities and skills, constituted, justified and organized through the arrangements of a social site, and mediated socially and materially with the aim of producing shared understanding and mutual agreement about ways of knowing and recognizing how performance is enacted, enabled and constrained in collective situated action.” However, as Cox^[13] points out, practice theory in itself is inconclusive. Corraid et al.^[67] highlight that practice-based approaches embrace a range of different perspectives both from an empirical and a theoretical stance. In describing the fluidity, or perhaps fragility of practice theory, these authors describe current work in practice theory as a “bandwagon.”

FROM THEORETICAL CONSIDERATIONS TO IMPLEMENTATION

Methodological approaches often follow similar pathways to those adopted to explore other frameworks and theories in LIS. For example, Tuominen et al.^[68] cite Garfinkel’s^[48] ideas on ethnography as an important means of exploring information practice, as well as the case study method used by researchers, such as Veinot.^[69] Savolainen^[11] cites Volosinov’s^[46] analysis through classification of concepts as a useful methodological approach. Among the wide array of available research techniques, interviews with individuals and textual analysis remain commonplace in data collection and analysis under the information practice approach.

Recent scholarship has drawn upon these explorations of discourse to theorize and apply an information practice approach to LIS research. As Buschman^[40] observes, there exists a core group of LIS scholars who have taken up the challenge of Harris^[70] and Wiegand^[49] to explore Foucault’s work and its implications for LIS theory and research. Leading works have emanated largely from Australia, North America, and the Nordic countries. For example, various publications by Talja, Tuominen, and Savolainen^[31,32,68] have explored positioning of information practice theoretically.

Examples of researchers implementing social constructionism as a research approach have expanded in recent years. Michael Olsson, who presented some of his early work on social constructionism at the ISIC conference held in Dublin in 2004,^[10] currently incorporates an information practice perspective into his previously information behavior-positioned research on Dervin’s sense-making and Foucault’s discourse analysis in his more

recent conference and published works.^[71–73] Sanna Talja, Annemaree Lloyd, Reijo Savolainen, and others have collaborated variously on works about information practices, for example Lloyd and Talja's edited volume focused on information practice, learning, and information literacy.^[74]

Pamela McKenzie, who has been acknowledged by many information practice scholars to be among the most highly active in this area,^[9] is known for implementing information practice in empirical fieldwork. For example, McKenzie^[75] has applied an information practice framework to clinical midwifery. McKenzie and Stooke^[76] also analyzed a public library storytime from a collectivist perspective, concluding that the approach enables the researcher to begin connecting the actions of individuals to those of social actors in other contexts. In her study of the information seeking accounts of pregnant women, McKenzie identifies four modes of information practices that she describes as operating on a continuum: "active seeking," "active scanning," "nondirected monitoring," and "by proxy."^[77] The first mode, as its title implies, is purposive, directed and planned information seeking. "Active scanning" would include practices in which the individual browses or scans materials or locations which are likely to offer information. McKenzie states that the third mode of information practice "... involves serendipitously encountering and recognizing a source... in an unlikely place, while not seeking information at all... or while monitoring information sources... with no intent other than to become generally informed." The final information practice mode in McKenzie's model is described as "by proxy" and includes a variety of incidents when an individual would obtain information through the intervention of an external agent or intermediary.

In 2007, McKenzie and Talja edited an issue of *Library Quarterly* (Vol. 77, No. 2), devoted to *Discursive Approaches to Information Seeking in Context*, with articles exploring topics related to communication, information literacy, and work and professional practices. Contributors included Savolainen,^[11] with his comparison of cognitive and discursive metatheories, as well as various authors applying information practice to different information contexts. Park^[78] analyzed a chat group's textual output to examine communication in an online environment. Veinot^[69] focused on a case study of the blue-collar work world of an individual vault inspector at a hydroelectric utility company, using information practice as a framework for exploration of an individual's work role. Lloyd^[8] applied information practice to the role of information literacy and workplace learning among firefighters in Australia, in which the process of increasing information literacy required interaction of various textual and personal constructions of collective practice. Having previously explored discourse in various other pieces individually, with others, and together,^[79,80] Johannisson and

Sundin^[81] examined embedded discourses in the nursing community of practice that produce a professional identity for this issue of *Library Quarterly*. Olsson^[82] investigated the relationships among author, text, reader, and researcher for Brenda Dervin as an author in LIS discourse, following on from previous work on this topic mentioned earlier^[10] and having presented this entry at the *ASIS&T annual conference* in 2005.^[83] Although individuals have previously published about information practice in various venues, this issue of *Library Quarterly* is significant for publishing several pieces on this subject in a single collection.

In more recent times, the authors have found a number of studies that either are grounded in a theoretical IP position^[12,63,69,84,85] or mention information practice(s) as an element of information behavior generally. The latter adopt an IB perspective and then describe practices that they categorize as part of the holistic information behaviors of those people they are studying.^[1–4,84–87] Of particular interest are Meyer's^[2] study of cross sociocultural information exchange with regard to developing communities that explores further Chatman's theory of small worlds, as well as Webber's^[4] and Huvila et al.'s^[11] investigations of the information behavior of individuals in "Second Lives" (SL), considering the rules and practices within this virtual reality that determine participants' active and passive information behaviors. From his work researching family photography, Cox^[14] argues that it is important for theorists and practitioners to engage in discussion about the use of practice theories to understand LIS as a social science. However, he also suggests perhaps a more pragmatic approach (i.e., "information in social practice") stating:

...information activities are woven through all social practices, and this is even more evident today through ubiquitous access to information resources through the internet. Thus we need to look at the information aspect of all social practices. Escaping a narrow preoccupation with goal-oriented information, we need to first ask within any practice what, for social actors, constitutes information, and then how do they find, use, create and share it^[14] (p. 185).

CONCLUSION: OPPORTUNITIES AND THEORETICAL PATHWAYS

It has been clearly established^[5] that IB is not fixated unilaterally on the cognitive dimensions of human being interactions with information,^[25,28] (etc.). Early models of human information behavior have firmly placed context at the core. The context includes the social dynamic that includes those customs, rules, attitudes, and vernaculars that comprise the multifaceted life worlds of each individual, experienced through their work, their membership in a

community and in their personal lives and familial histories. Equally, the unique individuality of the person contributes to the context. These elements not only dictate and determine the individual's information needs but as well direct the manner in which a person goes about finding information and subsequently how they use (or do not use) the information.

Rather than looking for ways to destabilize preliminary theory building semantically in this relatively new field in the social sciences, perhaps the way forward should be exploring the different perspectives of how to study, research, and think about human information behavior with a priority on the context.

The IP argument has and continues to be helpful in that it has provided a basis for scholars to explore further a multidisciplinary perspective in LIS. A pertinent and well-reasoned example would be Lloyd's work^[63] in applying Schatzki's site theory to information literacy practices. This type of work is to be welcomed in contributing to theory building. Equally, the IP stance and literature has fuelled others to challenge their discourse, with regard to everyday life information seeking and behavior to consider and reconceptualize the ways in which people engage, or do not engage, with information.^[13]

The different approaches described in this entry are "fluid and complementary," contributing to both practical and theoretical applications in LIS. Information practice offers a different approach to understanding information behavior. Although Savolainen^[11] argues that, while the cognitive approach has been the dominant discourse in LIS until recently, information practice "must be the primary discourse of LIS" in the future to enable understanding of everyday information worlds, the two perspectives continue to function in parallel in practice. For example, proponents of each approach present varying conceptual approaches in the recent text, *Theories of Information Behavior*,^[88] which takes information behavior as its umbrella concept. Similarly, researchers interested in information behavior and information practice participate together in events, such as the SIG USE connected with the ASIS&T, as well as the ISIC conference, supporting the notion and feasibility of co-existence. Advocates of the information practice approach credit some of these venues, such as ISIC, as the beginning of the rise of this rival umbrella concept.^[62] For the moment, at least, scholarship seems engaged in an exploration of new possibilities offered by different conceptual approaches.

The range of theoretical approaches offers a variety of choices to researchers exploring behaviors surrounding information. Each contributes to the scientific rigor of our research and the practical value of our efforts in delivering information services. Olsson^[82] offers several potentially fruitful areas of development, for example, Foucault's ideas about power offer inspiration in exploring the

relationship between power and information behavior. Other potential areas include nonpurposive information behavior, which remains largely unexplored, as well as a refocus on user expertise rather than knowledge gaps.^[82]

While some advocate separation and re-boxing of areas, perhaps the perspectives noted herein actually form an evolving continuum, along which a broad field of information behavior has emerged and from which we can draw upon to maximum benefit in our research. Olsson^[82] proposes an exciting future for the development of the field of information behavior, in which we can further Dervin and Nilan's^[89] call for a more holistic approach, noting "rather than conceiving of information behavior as being driven by the desire to satisfy discrete information needs, any information interaction or encounter should be seen as one chapter in an individual's ongoing engagement with, and construction of, their lifeworld."

Information Retrieval Experimentation [ELIS Classic]

Jean Tague-Sutcliffe

Graduate School of Library and Information Science, University of Western Ontario, London, Ontario, Canada

Abstract

Jean Tague-Sutcliffe was an important figure in information retrieval experimentation. Here, she reviews the history of IR research, and provides a description of the fundamental paradigm of information retrieval experimentation that continues to dominate the field.

—*ELIS Classic*, from 1996

INTRODUCTION

Information retrieval, the searching through collection of printed or electronic natural language material for items that may satisfy some individual's need or curiosity, has always been a core activity of information professionals. Research into the best way to carry out this activity has been a concern of information science since the field arose in the 1950s.

Information retrieval research belongs to the paradigm of empirical research. Theories are developed about the primary characteristics and relationships of the components of an information retrieval process. Hypotheses are developed about the effect of one or more factors, characteristics, or approaches (the independent variables) on the outcome of the process (the dependent variables). In experimentation, as opposed to other kinds of empirical research such as surveys, there is some control of the independent variable in order to determine the resulting change in the dependent variable.

Some of the components of an information retrieval process, as viewed by information retrieval researchers, are the collection or database that is being searched, the users, the query or verbalization of the user's need or interest, the searchers (end users or intermediaries), the search strategies or ways of searching to satisfy the user, the form of the output from a search, and the way the output is evaluated as to relevance or utility to the user. Each component can usually be further described by a number of characteristics that may vary and that may thus serve as independent variables in an experiment.

In a true laboratory experiment, all of the independent variables and other factors that might affect the outcomes are under the control of the experimenter. In an operational test, at least some will be determined by the operational setting. Some writers would restrict the word *experiment* to the laboratory setting. However, in information retrieval research, there is really a spectrum of researcher control, from situations in which

database, searchers, queries, search strategies, and output are all controlled by the experimenter, to situations in which some components are controlled and others are not, to situations in which only one component is controlled. In this entry, we will consider all situations in which there is control of at least one independent variable.

In any information retrieval experiment, the researcher will use databases and develop search strategies and forms of output that embody the variable features, the hypotheses, that he or she is investigating. In a laboratory experiment, all other aspects of the retrieval process will be held constant. At one time, information retrieval researchers ensured an even greater control by creating artificial queries and relevance determinations. A number of test collections of documents and queries with predetermined relevance assessments were developed and used to test a variety of hypotheses. The predominant present-day view of information retrieval, however, is that queries must represent real user needs and that the end user can best determine the relevance or utility of the output with respect to this need.

The advantage of a laboratory experiment is that the control of extraneous sources of variation makes it possible to draw conclusions about the effect of the features under investigation in terms that are not limited to the particular situation in which the retrieval took place. In operational tests, it is not always possible to conclude that the features under investigation really caused the observed results because there are so many uncontrolled sources of variation. However, laboratory tests have their disadvantages: they are expensive to set up, and incorporating real users and queries in a laboratory environment is difficult. If the experimental database is small or if real users and queries are not employed, the results may not apply to operational systems. However, as Hull^[1] and Salton^[2] have pointed out, there is no reason to disallow experiments with small experimental systems unless specific biases can be demonstrated.

The situation is not really one of “either/or” but of “both.” Robertson and Hancock-Beaulieu^[3] suggest that given the complexity of present-day information retrieval systems and the need to take user characteristics into account, the best solution is a facility intermediate between a laboratory and an operational environment. Called the evaluative facility, this would use real users, queries, and databases, but provide capabilities for easy modification of query and document representations and extensive data gathering and analysis.

Many different features of information retrieval systems have been evaluated in information retrieval research. Most attention has been paid to the way items are represented in the database and the way searches are carried out. In early experiments, the database usually consisted of a set of document surrogates, records that referenced, indexed, and abstracted printed documents outside the system. In more recent times, databases may consist of full-text documents or even hypertext or hypermedia documents, in which the user peruses the document via links, rather than in a predetermined sequence.

The ways in which information is represented in the database and the search strategies are closely related. This relationship can be described by an information system model. A number of these have been developed, the most prominent being the Boolean model and the vector space model. Much information retrieval experimentation has focused on aspects of these two models or on comparisons of the two.

In the Boolean model, the documents in the database are represented as sets of index headings, keywords, or descriptors (called *terms*), possibly with field delimiters such as author, title, abstract, and journal source. Search strategies consist of Boolean expressions involving these terms, possibly delimited, and the Boolean operators “and,” “or,” and “not.” For example, the search expression “interface and (database or information)” would retrieve documents containing the term *interface* and either *database* or *information*. The output from a Boolean model system is a set of retrieved documents.

In the vector space model, both documents and queries are represented as sequences or vectors of weights, one for each term in the database. The weight is a number, usually between zero and one, that indicates the importance of the term in the document or query. Search strategies determine the similarity of document and query using these weights and output documents ranked by this similarity value.

PERFORMANCE MEASURES

A number of performance measures have been used by information retrieval researchers as a basis for comparing different systems features. The best known are recall and precision, originally suggested by Perry et al.^[4] in 1956.

They are based on the idea that the purpose of a retrieval system is to present the users with all and only those documents that are relevant to their information needs. Recall is the proportion of the documents relevant to the user that are retrieved by the search. Precision (originally called pertinency) is the proportion of the documents retrieved by the search that are relevant to the user. Both recall and precision represent properties that are important to the user, however, they assume that the user can unambiguously identify relevant documents for an information need, an assumption that has been questioned by a number of investigators, for example Saracevic.^[5]

Relevance may not be a binary variable; some investigators have used a ternary scale (relevant, partially relevant, not relevant), others an ordinal scale (i.e., documents are ranked as to relevance), and still others a continuous scale. A distinction is often made between subject relevance (aboutness) and usefulness (pertinence), although Regazzi^[6] found experimental evidence of no difference in subjective judgments of subject relevance and utility. Some investigators believe that relevance requires assessment by the end user, the person with the information need, although Burgin^[7] found that variations in relevance judgments by four judges did not affect retrieval performance. Finally, Schamber et al.^[8] suggest that the relevance of a document is situational and dynamic in that it depends on what the user has already seen.

Despite these difficulties, binary relevance-based values continue to be the basis for evaluation of information retrieval features. Recall and precision are sometimes supplemented with fallout, defined as the proportion of nonrelevant documents that are retrieved. Fallout provides additional evaluative information, as it is sensitive to the size of the collection. For example, a search of a 1,000- and a 1 million-document database could produce the same recall and precision values. However, the search of the 1 million-document database would clearly be superior in terms of discriminating power, and this fact would be evident in the two fallout values.

In some retrieval experiments, performance measures reflect aspects of the retrieval process other than search effectiveness. The efficiency of the data structures and processing algorithms may be measured by such temporal variables as user connect time or number of disk accesses. In experiments concerned with features of the user-system interface, user friendliness may be assessed via user rating scales or more objective criteria such as length of learning time or number of exasperation responses or terminations.

Subjective ratings of overall system success are seen by some investigators (e.g., Su^[9]) as being superior to the more objective measures of recall and precision. However, system success is an even more elusive concept to define than relevance, and in most studies in which it is recorded, shows very little variation over users or features. Thus, it can rarely be used in an experimental setting to discriminate good performance from bad.

Hypertext and other interactive full-text systems have complicated the evaluation problem. Users follow search trails, rather than receiving sets of retrieved items. Tague-Sutcliffe^[10] suggests that evaluation should compare the actual search trail with an “ideal” one for the user. Ways of describing user actions become important in evaluating information retrieval systems; for example, Qiu^[11] suggests that user trails can be described as Markov processes, sequences of search states with certain probabilistic dependencies.

MAJOR INFORMATION RETRIEVAL EXPERIMENTS

Information retrieval experimentation is usually considered to have begun in the late 1950s with the Cranfield tests by Cyril Cleverdon.^[12–14] In Cranfield I, a comparative evaluation was made of four systems: the universal decimal classification (UDC), a conventional alphabetical subject index, a facet classification, and Uniterm (keyword) coordinate indexing. During the test, 18,000 papers in the field of aeronautical engineering were indexed by each of the four systems, and 1,200 search questions were obtained from several hundred individuals for questions based on a single document. The search was considered successful if that document was retrieved. The results showed all four systems retrieved the required paper in 74–88% of the cases, with the Uniterm system scoring the highest and faceted classification the lowest. Most failures were due to human error rather than the indexing system. A later comparison with the computer-based metallurgical index at Western Reserve University,^[14] which employed sophisticated language analysis features (role indicators and semantic factors), showed that the performance of the new system was not equal to that of the four original systems.

Cranfield II, also carried out by Cleverdon, sought to determine the effect of specific recall-increasing and precision-increasing devices in a laboratory setting. Questions were obtained from 200 authors of recently published papers who were asked to provide questions to which their paper would be an answer. A test collection of 1,400 documents and 279 questions were obtained in this way. The indexing languages evaluated consisted of single terms selected from the natural language of the document, alone or combined with various devices such as synonyms, word form variants, quasi-synonyms, term weighting, links and roles, hierarchical linking of terms, phrases, and controlled language terms. Ranked output was obtained by using ten coordination levels.

Indexing devices were evaluated by a single measure, normalized recall, which is essentially recall averaged over the points in the search where relevant documents are retrieved. The results showed that indexing based on single natural language terms, the simplest kind of

indexing to implement, performed best by this criterion. The number of index terms assigned to documents, or exhaustivity, was also found to influence performance, with the optimal level being one of thirty-three terms.

Cleverdon,^[12] speaking of these tests from a perspective of 30 years, notes that although he found the results of Cranfield II more significant than the earlier tests, “they did not arouse so much general comment, partly, I think, because the results were so unexpected as to appear unbelievable and also because the nature of the test removed it so far from normal experience.” He also notes that the tests confirmed the hypothesis that there is an inverse relationship between recall and precision, so that there are no devices that concurrently increase both.

The Cranfield II test collection was subsequently used by two other information retrieval experimenters, Gerard Salton at Cornell University and Karen Sparck Jones at Cambridge University. Salton^[2] has developed and used an experimental system, the Smart system, over a period of 30 years, to investigate a number of sophisticated approaches to information retrieval based on the vector space model and a ranked output. The earlier tests are described in Salton^[15] and Salton and McGill,^[16] and later ones in a series of papers, many of which are listed in the references to Salton’s 1992 article.^[2] Early results showed that weighted word stem indexing, where the stems are extracted from the document texts, was more effective than such sophisticated methods as phrases and classification hierarchies. A comparison with a subset of the Medlars search system at the National Library of Medicine, which uses a controlled vocabulary, showed that the Smart word stems increased recall by 12% and decreased precision by 9%.^[17]

In recent years, the Smart collection has grown to approximately 50,000 documents distributed over six test collections. Each collection covers a different subject area, and queries and relevance assessments have been obtained from a number of different user populations. Improvements, as evaluated by precision averaged over standard recall levels, have been obtained through sophisticated term weighting procedures, relevance feedback techniques, and extended Boolean logic. The optimal term weighting in noninteractive retrieval was found to be a normalized function of the within document frequency divided by the across documents frequency. Relevance feedback is a process in which the results from an initial search, evaluated by the user, are used to supplement and reweight the original query terms to provide a revised query, which can then be used to search the database again. Extended Boolean retrieval includes a set of techniques that permit a ranking of documents retrieved by a Boolean search. Thus, it allows comparison of the output of Boolean and vector space systems.

Another early set of experiments in information retrieval was performed at Cambridge University by Karen Sparck Jones and Roger Needham. Here the interest

was in automated classification, and a series of investigations as carried out^[18,19] to discover why classification techniques did not prove in experiments to be as effective as simple keyword indexing. Despite a major series of tests concluded in 1976, Sparck Jones was unable to isolate the reasons for failure of classification to improve retrieval. It was at this point that she and Van Rijsbergen proposed the development of the ideal test collection^[20] to provide a resource that could be used by the international information retrieval community to test new approaches to retrieval. Although the collection did not materialize at that point, the proposal provided the seed for the TREC tests of the 1990s.

In the 1980s, Tefko Saracevic, Paul Kantor, and others conducted a major series of information retrieval experiments at Case Western Reserve University.^[21] These tests used a more operational environment than those just described; the aim of the study was to investigate the elements involved in information seeking and retrieving, particularly related to the cognitive and human decision-making context, in conditions as close to real life as possible.

Forty users were involved, each of whom submitted one question for searching, evaluated items retrieved as to relevance for this question, and provided other information via questionnaire and interview. Each question was searched by nine different searchers from a pool of thirty-nine searchers. Searching was done on DIALOG, with one database searched for each question. The analysis investigated the impact of a number of variables on precision and recall and on the odds that retrieved items were relevant as opposed to not relevant.

An interesting finding of the experiment related to the overlap in search terms used by different searchers. Based on 800 pairs of comparisons, the main overlap was only 27% in search terms and 18% in items retrieved. Items retrieved five or more times were over six times as likely to be relevant or partially relevant as items retrieved once. In general, the more often an item was retrieved by different searchers for the same question, the more likely it was to be relevant.

A number of statistically significant results were found in this study. These were presented in the form of an increase in the odds that (1) items retrieved in association with a given characteristic of a variable would be relevant or partially relevant as opposed to not relevant, and (2) searches associated with a given characteristic of a variable would be of high precision and recall, as opposed to low precision or recall. Recall, in this case, meant relative recall; that is, the proportion of the relevant documents found by any searcher that were found in one particular search for a question.

The following variables increased the indicated odds by a factor of at least two: placing a time limit on years searched increased precision odds; low subject specificity and high complexity in the question increased precision

odds; high searcher scores for abstractness over concreteness increased precision and recall odds; and finally, retrieval by four or more searchers increased relevance odds more than any other variable.

A challenge to the validity of results from a small database was presented by the Blair and Maron full-text evaluation of the 1980s.^[22] They investigated the Boolean-based IBM STAIRS full-text document retrieval system by using it to search approximately 350,000 pages of text in a litigation support system. Some 51 queries were generated by two lawyers, who evaluated retrieved documents as relevant (vital, satisfactory, marginally relevant), or irrelevant. Searching was continued until the user stated that he or she was satisfied with the result and believed that at least 75% of the relevant documents had been retrieved. To find the unretrieved relevant documents, in order to estimate recall, the investigators generated samples of subsets of the database they believed to be rich in relevant documents. These samples were also evaluated by the users.

Average precision was 75.5% and average recall 20.3%. The investigators speculate that recall was low because "it is impossibly difficult for users to predict the exact word, word combinations, and phrases that are used by all (or most) relevant documents and *only* (or primarily) by these documents."^[22] They suggest that previous results, based on small experimental databases, cannot be transferred to larger operational databases.

Partly in response to this concern that experiments must use realistically sized test collections, the TREC (Text Retrieval Conference) project was launched by Donna Harman in 1992, under the sponsorship of the U.S. National Institute of Standards and Technology and the U.S. Advanced Research Projects Agency. The purpose of the TREC project is to provide a forum in which researchers using a variety of approaches to information representation and retrieval can compare these approaches using a large collection of textual materials, queries and associated relevance judgments, and a uniform scoring procedure. TREC conferences were held in 1992, 1993, and 1994.

TREC is designed to evaluate both ad hoc (one-time) querying and routing (filtering) searches. Participants work with approximately 1 million documents, retrieving lists of documents for fifty ad hoc and fifty routing queries. Queries may be automatically or manually constructed and may use relevance feedback. Test data consist of newspaper stories, Associated Press newswire entries, U.S. patent applications, entries from the *Federal Register*, the Ziff Computer Select database, and U.S. Department of the Environment abstracts.

The National Institute of Standards and Technology is responsible for the distribution of the test data, the evaluation of the outputs, and the analysis of the results. Relevance judgments are made by assessors at the institute of the top 100 documents from each participant for each

query. Evaluation involves the calculation of precision at standard recall levels (0, .1, .2, .3, .4, .5, .6, .7, .8, .9, 1), precision at fixed numbers of retrieved documents (5, 10, 15, 20, 30, 100, 500, 1000), and two average precision values (over standard recall levels and over the first R retrievals, where R is the number of relevant documents for the query).

There were 25 participating systems in TREC-1 and each participant submitted ranked lists of the top 200 documents retrieved for each topic. Much of the participants' time was spent in organizing the large dataset, so that results were very preliminary in nature. Harman summarizes TREC-1 by saying:^[23]

it was clear that the simple systems did the task well, but it is too early to pass judgment on the more complicated systems. The automatic construction of queries from the topics did as well as, or better than manual construction of the queries, and this is encouraging for groups supporting the use of simple natural language interfaces for retrieval systems.

There were thirty participants in TREC-2 and each group submitted ranked lists of the top 1,000 documents retrieved for each query. In general, TREC-2 results showed an improvement in effectiveness over TREC-1, in part because of the submission of a larger number of retrieved documents (1,000 rather than 200) and in part because of participants' greater experience with the data and their systems.

Approaches in TREC-2 included probabilistic models, vector space models, natural language processing, Bayesian networks, query expansion, Boolean models, combinations of strategies, and document structuring. A preliminary report^[24] notes that, as in TREC-2, the simple systems still did the best, but the more complex ones are catching up. Term weighting emerged as being especially important. Harman also notes a problem in looking solely at average measures: "there were 21 groups for which there was at least one topic on which their system had the best average precision."

The TREC tests are likely to continue to set the standard in information retrieval testing for the 1990s, however, it is also likely that more attention will be paid in the future to what is happening at the individual document-query level, using techniques such as failure analysis and analysis of passages (rather than documents) retrieved.

CURRENT RESEARCH CONCERNS

As we have seen, the two major concerns of past retrieval experimentation were first, how documents should be represented in a database, and second, how search strategies should be structured so as to retrieve all and only the relevant documents. These concerns continue to be the

focus of much current information retrieval experimentation, as reflected in the *Proceedings of the ACM SIGIR International Conference on Research and Development in Information Retrieval* and other sources listed at the end of this entry.

Recent research has tended to investigate more complicated approaches than simple document-query keyword matching and to look at the interfaces and special features needed for particular applications. In this entry, we will describe some recent work of particular interest, although it should be understood that this description represents a sampling only and is by no means complete.

A key aspect of the vector space model is the weighting of query terms. Robertson and Sparck Jones^[25] introduced an important model, called the probabilistic model, for this weighting; term weights should represent the logarithm of the odds in favor of relevance over nonrelevance for documents indexed by the term. The technique of relevance feedback, in which the user evaluates as relevant or nonrelevant an initial set of documents, makes possible an estimate of these odds for the original and for new query terms. Harman^[26] found in experiments on relevance feedback with the Cranfield collection that most improvements in retrieval using relevance feedback come from the addition of a limited number of new query terms. She also found that multiple iterations of feedback are very effective. Aalbersberg^[27] notes that despite positive experimental results, relevance feedback has not been implemented in commercial systems because of the user friendliness problem. He suggests a "friendlier" approach (incremental relevance feedback), in which documents are retrieved one at a time and relevance judgments are made directly after documents are retrieved.

Many other experiments in recent years have addressed the problem of optimal methods of term weighting and query expansion. Keen^[28] has experimented with document-ranking principles that are based on term position or the proximity of the query terms in the sentences of the document. He found that incorporating term position improved precision by 12–18%, depending on recall. Crouch and Yang^[29] and Grefenstette^[30] experimented with techniques for extending the querying by automatically generating thesaurus classes, lists of words related to the original query terms.

Despite the poor results that phrase-based indexing, as opposed to simple word retrieval, has produced in the past, a number of investigators have looked at more sophisticated ways of incorporating phrases into retrieval. Fagan^[31] showed that incorporation of statistical phrases, defined by co-occurrence and proximity of words, sometimes improved retrieval, but that imposing syntactic constraints as well did not result in further improvements. Croft et al.^[32] extend Fagan's work by incorporating weights that represent the importance of the phrase, as distinct from the individual terms, in the document and query.

Investigators continue to be concerned that retrieval is based on word stems rather than on concepts and have suggested various forms of analysis to overcome the “limitations” of uncontrolled word stem indexing. Linguistic analysis may be used to disambiguate word senses when a word may have more than one meaning. Voorhees^[33] experimented with an automatic indexing procedure that uses WordNet, a thesaurus containing hierarchically organized sets of synonyms, to carry out this task. Thus, it permits the construction of vectors of word senses rather than word stems. Deerwester et al.^[34] looked at latent semantic analysis, which permits documents to be represented by factors rather than terms. The factors are obtained as weighted combinations of the initial word stems.

Information retrieval systems are increasingly based on collections of full-text documents rather than document surrogates. Thus, the problem of passage retrieval, retrieving the passage or passages within a document that best answers a query, has become an important concern of information retrieval experiments. O'Connor^[35] carried out experiments on passage retrieval in the 1970s. More recent work experiments have been done by Salton, Allen, and Buckley.^[36] An interesting aspect here relates to the size of the text fragment that should be output and whether or not several text fragments should be combined in an “answer.”

Boolean retrieval methods also continue to be investigated. Croft et al.^[32] suggest that translating natural language queries into Boolean expressions using “and,” “or,” and “not” may be more effective than the vector space model of sets of weighted terms, and they have developed some experimental evidence for this statement. The work of Saracevic and Kantor^[21] showed that different searchers tended to generate different strategies for the same query. Similarly, Turtle and Croft^[37] found that combining natural language and Boolean combinations for the same query increased performance over either one alone. Belkin et al.^[38] experimented with five independently generated Boolean query formulations and found that progressive combination of query formulations leads to progressively improving retrieval performance. Pao^[39] found that using both term and citation searching on commercial databases improves recall and discrimination of relevant items.

In cluster-based retrieval, documents are grouped together on the basis of similarity in their term vectors. The expectation is that search time will be reduced by confining the search to a subset of clusters. Experiments with clustering have focused on optimal methods for their construction (see, e.g., Willett)^[40] and on the question of their meaning; that is, if they represent meaningful groupings or if they are simply random collections of documents. Shaw^[41] looked at evidence for clustering structure and the effectiveness of cluster-based retrieval and found an inverse relationship between them.

EXPERIMENTAL DESIGN AND ANALYSIS

In general terms, the problem in information retrieval is to assess the effects of one or more factors or independent variables on a performance measure by means of a sample of experimental units in which each unit is assigned to a combination of factor levels and measured as to performance. Experimental design is concerned with techniques for assigning the experimental units to the factor levels. In order to eliminate bias, it is essential that units be assigned randomly, and in order to assess interactions between variables, it is essential that more than one unit be assigned to combinations of factors.

Information retrieval experiments, the independent variables are the features of the database, the search strategies, the queries, and the users that we are investigating. Other factors relating to the search environment, such as the characteristics of the searcher, the order of searching, equipment problems, time, and temperature, may also affect the outcome and so should be randomized as much as possible over the factors that are of particular concern.

What constitutes an experimental unit in an information retrieval research design will depend on the purpose of the experiment, but in general it will be the smallest unit for which performance is measured. For example, an experimental unit might be a query, a search for documents relevant to the query using one particular strategy, a search using one particular strategy by one particular searcher, a single document retrieved in a search, or a step in a search process. Performance may be measured for each of these, depending on the kind of performance (query-level, strategy-level, searcher/strategy level, document-level, search-step-level).

In a minimal information retrieval experiment, there will be treatments (search strategies or indexing approaches) and queries. A major decision is whether or not to search different queries under the various treatments (independent samples) or repeatedly search each query under all treatments (repeated measures). The advantage of repeated measures is that variation in the difficulty of the query topics will not affect the overall results. The disadvantage is that there may be learning or fatigue effects (sequence effects) as a searcher repeats the same query using a different treatment. Different searchers may be used for each repetition; however, this will not be possible if searching is to be done by the end user.

To eliminate some of the variability among queries in the independent sample design a randomized block design may be used. Here the queries are separated into a number of blocks or groups of queries at approximately the same level of difficulty. Equal numbers of queries from each block are then assigned to the treatments and constitute independent samples. More complicated designs are used when there is more than one kind of treatment. Several of these are described in Tague-Sutcliffe.^[42]

Fig. 1 Interpolated precision at standard recall levels.

Results of information retrieval experiments are usually presented in the form of averages of recall and precision values or, when output is ranked as with the vector-space model, in the form of recall-precision graphs. The most commonly used recall-precision graph shows interpolated precision values at standard recall values from zero to one. Another form shows precision at fixed numbers of retrieved documents. Both forms are shown in Figs. 1 and 2, which present these graphs for two of the participants in TREC-2.

Standard techniques of statistical analysis may be used to test hypotheses regarding differing effects of the treatments or factors in an information retrieval experiment. Analysis of variance may be used to compare mean performance scores for different treatments if the original scores satisfy the assumptions of this technique, namely approximate normality and equality of variance over treatment groups. If these assumptions are not met, then it may be necessary to transform the scores; in particular, it is often helpful to transform recall and precision scores by applying an arcsine transformation to their square root in order to stabilize the variance. If performance scores do not satisfy the requirements of ANOVA, as would be the case if they were ordinal rather than quantitative,

Fig. 2 Precision at retrieved document levels.

nonparametric statistical techniques are used. Hull^[1] provides an overview of both classical and nonparametric techniques that may be used in analyzing results of information retrieval experiments.

FUTURE DIRECTIONS

As text and multimedia collections continue to grow worldwide, the core problem of information retrieval—to give the user all and only that information that he or she needs—remains to be solved and, indeed, may be unsolvable. Many subproblems remain, though, that are tractable, and information retrieval research is therefore unlikely to decline.

Some specific problems that have been identified by researchers in the field and that are amenable to the experimental approach are listed below:

- Under what conditions can results from small-scale experiments be applied to large operational systems?
- How can we model user behavior in interactive windowed information retrieval environments in such a way as to be able to use the model to improve retrieval systems?
- Using the Schamber et al.^[8] dynamic situational view of relevance, how can we determine the document characteristics that should be in the system in order to satisfy this kind of relevance criteria?
- What kinds of experiments can be designed to improve the user interface to an information retrieval system?
- How can efficiency as well as effectiveness of information retrieval processes be investigated by information retrieval experiments?
- How can information retrieval experimental research have a greater impact on commercial systems development?
- Will Cranfield I ever be disproved?

SOURCES

The best source of information about current information retrieval experimentation is the *Proceedings of the ACM SIGIR International Conference on Research and Development in Information Retrieval*, published by the Association for Computing Machinery (ACM) Special Interest Group in Information Retrieval. Two other ACM publications frequently contain entries about information retrieval experiments: *Transactions on Information Systems* and *Communications of the ACM*. Information science journals such as *Information Processing and Management*, and the *Journal of Documentation* also publish experimental retrieval studies. The July-August 1992 issue of *Information Processing and Management*

(vol. 28, no. 4), a special issue on evaluation issues in information retrieval, is particularly useful.

Only one book is exclusively devoted to information retrieval experiment: *Information Retrieval Experiment*; edited by Karen Sparck Jones (Butterworths, London, 1981). Despite the date, it still contains much valuable information. A good general introduction to information retrieval is *Information Retrieval: Data Structures and Algorithms*; edited by W. B. Frakes and R. Baeza-Yates (Prentice-Hall, Englewood Cliffs, N.J., 1992)^[43].

Encyclopedia of Library and Information Sciences, Fourth Edition

Contents

Volume I

Academic Libraries / Susan Curzon and Jennie Quiñónez-Skinner	1
Accessibility / Lori Bell	14
Accreditation of Library and Information Studies Programs in the United States and Canada / Karen Lynn O'Brien	18
Acquisitions Institute at Timberline Lodge / Scott A. Smith	22
African Librarianship / Natalia T. Bowdoin and Janet Lee	33
Altmetrics / Richard Cave	44
American Association of Law Libraries (AALL) / Kate Hagan	48
American Association of Museums (AAM) / Elizabeth E. Merritt	56
American Association of School Librarians (AASL) / Donald C. Adcock	59
American Library Association (ALA) / Mary W. Ghikas	67
American Medical Informatics Association (AMIA) / Don E. Detmer, Tia Abner and Karen Greenwood	85
American National Standards Institute (ANSI) / Jana Zabinski	87
American Society for Information Science and Technology (ASIST) / Charles H. Davis and Debora Shaw	90
Approval Plans / Robert Nardini	96
Arab Federation for Libraries and Information (AFLI) / Nour Soufi	100
Archival Appraisal and Acquisition / Barbara Reed	105
Archival Arrangement and Description / Joanne Evans, Sue McKemmish and Barbara Reed	115
Archival Documentation / Gavan McCarthy and Joanne Evans	127
Archival Finding Aids / Su Kim Chung and Karla Irwin	133
Archival Management and Administration / Michael J. Kurtz	141
Archival Reference and Access / Mary Jo Pugh	149
Archival Science / Elizabeth Shepherd	166
Archives / Adrian Cunningham	179
Archivists and Collecting / Richard J. Cox	195
Area and Interdisciplinary Studies Literatures and Their Users / Lynn Westbrook	209
ARMA International, Inc. / Carol E. B. Choksy	221
Armenia: Libraries, Archives, and Museums / Sylva Natalie Manoogian	228
Art Galleries / Daniel C. Danzig	241
Art Librarianship / Kathryn M. Wayne	249
Art Museums / David Gordon	259

Volume I (cont'd.)

Artificial Intelligence / Jianhua Chen	269
Artificial Neural Networks and Natural Language Processing / Hermann Moisl	279
Arts Literatures and Their Users / Lisl Zach	293
ASLIB / David Bawden and Lyn Robinson	301
Association for Information Science and Technology / Diane H. Sonnenwald, Charles H. Davis and Debora Shaw	311
Association for Information Systems (AIS) / William R. King and Dennis Galletta	318
Association for Library Collections and Technical Services / Charles Wilt	324
Association for Library Service to Children (ALSC) / Virginia A. Walter	333
Association of College and Research Libraries (ACRL) / Mary Ellen Davis and Mary Jane Petrowski	338
Association of Library Trustees, Advocates, Friends and Foundations (ALTAFF) / Sally Gardner Reed	361
Association of Research Libraries (ARL) / Lee Anne George and Julia Blixrud	364
Association of Specialized and Cooperative Library Agencies (ASCLA) / Barbara A. Macikas	376
Australia: Libraries, Archives, and Museums / Alex Byrne	379
Australian Library and Information Association (ALIA) / Sue Hutley, Jane Hardy and Judy Brooker	396
Authentication and Authorization / David Millman	401
Automated Acquisitions / Patricia A. Smith and Allison V. Level	408
Automatic Abstracting and Summarization / Daniel Marcu	418
Automatic Discourse Generation / John A. Bateman	430
Back-of-the-Book Indexing / Nancy C. Mulvany	440
Bibliographic Control [ELIS Classic] / Robert L. Maxwell	447
Bibliographical Society (London) / Julian Roberts	456
Bibliographical Society of America (BSA) / Hope Mayo	463
Bibliography / D. W. Krummel	468
Bibliometric Overview of Information Science / Howard D. White	480
Bibliometric Research: History [ELIS Classic] / Dorothy H. Hertz	492
Bibliothèque Nationale de France / Noémie Lesquins	531
Binding [ELIS Classic] / Lawrence S. Thompson	538
Biological Information and Its Users / Kalpana Shankar	554
Blind and Physically Disabled: Library Services / Jane Rosetta Virginia Caulton and Stephen Prine	563
Bliss Bibliographic Classification First Edition [ELIS Classic] / Jack Mills	573
Bliss Bibliographic Classification Second Edition / Vanda Broughton	581
Boolean Algebras [ELIS Classic] / A. R. Bednarek	591
Brazil: Library Science / Mariza Russo	597
Brazil: Library Science—Distance Education / Mariza Russo	603
Brazil: Museums / Regina Dantas and Pamela Howard-Reguindin	611
British Library / Andy Stephens	616
Business Informatics / Markus Helfert	630
Business Information and Its Users / Eileen G. Abels	635
Business Literature: History [ELIS Classic] / Edwin T. Coman, Jr.	643
Canada: Libraries and Archives / Ian E. Wilson and Sean F. Berrigan	654
Canadian Heritage Information Network (CHIN) / Shannon Ross and Paul M. Lima	675
Canadian Library Association (CLA) / Donald I. Butcher	681
Careers and Education in Archives and Records Management / Karen Anderson	685
Careers and Education in Information Systems / Paul Gray and Lorne Olfman	693

Volume I (cont'd.)

Careers and Education in Library and Information Science / <i>Jana Varlejs</i>	706
Careers and Education in Records and Information Management / <i>Carol E. B. Choksy</i>	715

Volume II

Cataloging / <i>Daniel N. Joudrey</i>	723
Cataloging Cultural Objects (CCO) / <i>Elizabeth O'Keefe and Maria Oldal</i>	733
Catalogs and Cataloging: History [ELIS Classic] / <i>Eugene R. Hanson and Jay E. Daily</i>	743
Censorship and Content Regulation of the Internet / <i>Peng Hwa Ang</i>	780
Center for Research Libraries / <i>Mary I. Wilke</i>	789
Charleston Conference / <i>Katina Strauch</i>	794
Chartered Institute of Library and Information Professionals (CILIP) / <i>Tim Owen</i>	806
Chemistry Literature and Its Users [ELIS Classic] / <i>Judith N. Currano</i>	814
Chemoinformatics / <i>Peter Willett</i>	830
Children and Information Technology / <i>June Abbas</i>	839
Children's Literature / <i>Judith V. Lechner</i>	852
Children's Services in Libraries / <i>Virginia A. Walter and Melissa Gross</i>	876
China: Libraries, Archives, and Museums / <i>Priscilla C. Yu and TzeHuey Chiou-Peng</i>	886
Circulation Services / <i>Vanessa Irvin and Jeff E. Bullard</i>	916
Citation Analysis / <i>Howard D. White</i>	923
Citation Indexes and the Web of Science / <i>Marie E. McVeigh</i>	940
Citer Motivations [ELIS Classic] / <i>Terrence Brooks</i>	951
Classification Theory / <i>Clare Beghtol</i>	958
Clinical Decision-Support Systems / <i>Kai Zheng</i>	974
College Libraries / <i>Thomas G. Kirk, Jr.</i>	983
Communication and Communication Studies / <i>Brenda Dervin and CarrieLynn D. Reinhard</i>	994
Communication Policy: United States / <i>D. Linda Garcia</i>	1007
Community Informatics / <i>Kate Williams and Joan C. Durrance</i>	1027
Complexity and Self-Organization / <i>Francis Heylighen</i>	1034
Computer-Mediated Communication (CMC) / <i>Michael A. Chilton and Roger McHaney</i>	1044
Computer-Supported Cooperative Work (CSCW) / <i>Kevin L. Mills</i>	1053
Conservation and Preservation of Museum Objects / <i>Ellen Pearlstein</i>	1068
Controlled Vocabularies for Art, Architecture, and Material Culture / <i>Murtha Baca</i>	1076
Corporate Archives / <i>Philip Mooney</i>	1081
Corporate Art Collections / <i>Laura Matzer</i>	1086
Corporate Information Centers / <i>Barbara M. Spiegelman and Nancy Flury Carlson</i>	1094
Corporate Records Management / <i>Barbara M. Cross and Barbara E. Nye</i>	1104
Credibility and Cognitive Authority of Information / <i>Soo Young Rieh</i>	1113
Croatia: Libraries, Archives, and Museums / <i>Aleksandra Horvat, Josip Kolanović and Višnja Zgaga</i>	1121
CrossRef Publisher Linking Network / <i>Amy E. Brand</i>	1132
Cultural Memory / <i>Robert DeHart</i>	1139
Curating Archaeological Artifacts / <i>Alex W. Barker</i>	1147
Curating Natural History Collections / <i>Kimberly S. Bostwick</i>	1156
Custody and Chain of Custody / <i>Bernadette G. Callery</i>	1164
Data and Data Quality / <i>Thomas C. Redman and Christopher Fox and Anany Levitin</i>	1171
Deaf and Hearing Impaired: Communication in Service Contexts [ELIS Classic] / <i>Warren R. Goldmann</i>	1183

Volume II (*cont'd.*)

Decision Sciences / <i>Sven Axsäter and Johan Marklund</i>	1192
Decision Support Systems / <i>Marek J. Druzdzel and Roger R. Flynn</i>	1200
Demand-Driven Acquisition/Patron-Driven Acquisition / <i>Michael Levine-Clark</i>	1209
Denmark: Libraries, Archives, and Museums / <i>Jens Thorhauge, Jakob Heide Petersen and Ole Magnus Mølbak Andersen</i>	1215
Descriptive Cataloging Principles / <i>Elena Escolano Rodríguez</i>	1229
Design Science in the Information Sciences / <i>Judith Weedman</i>	1242
Dewey Decimal Classification (DDC) / <i>Joan S. Mitchell and Diane Vizine-Goetz</i>	1256
Digital Content Licensing / <i>Paul D. Callister and Kathleen Hall</i>	1267
Digital Divide and Inclusion / <i>Mark Warschauer and Melissa Niiya</i>	1279
Digital Humanities / <i>Julia Flanders and Elli Mylonas</i>	1286
Digital Humanities and Academic Libraries / <i>Bobby Smiley and Michael Rodriguez</i>	1298
Digital Images / <i>Melissa Terras</i>	1307
Digital Millennium Copyright Act of 1998 / <i>Jonathan A. Franklin</i>	1316
Digital Object Identifier (DOI®) System / <i>Norman Paskin</i>	1325
Digital Preservation / <i>Jacob Nadal</i>	1332
Diplomatics / <i>Luciana Duranti</i>	1338
Disaster Planning and Recovery for Cultural Institutions / <i>Sheryl Davis, A. Patricia Smith-Hunt and Kristen Kern</i>	1347
Document Information Systems / <i>K. van der Meer</i>	1360
Document Theory / <i>Niels Windfeld Lund and Roswitha Skare</i>	1372
Document Type Definition (DTD) / <i>Judith Wusteman</i>	1381
Dublin Core Metadata Initiative (DCMI): A Personal History / <i>Stuart L. Weibel</i>	1390
Economics Literature: History [ELIS Classic] / <i>Arthur H. Cole and Laurence J. Kipp</i>	1399
Electronic Records Preservation / <i>Robert P. Spindler</i>	1413
Electronic Resources & Libraries (ER&L) / <i>Jesse Koennecke</i>	1419
Encoded Archival Description / <i>Daniel Pitti and Michael Rush</i>	1423
Engineering Literatures and Their Users [ELIS Classic] / <i>Thomas E. Pinelli, Ann P. Bishop, Rebecca O. Barclay and John M. Kennedy</i>	1433

Volume III

Epistemology / <i>Paul K. Moser</i>	1455
Ethical and Legal Aspects of Archival Services / <i>Sara S. Hodson</i>	1463
Ethical Aspects of Library and Information Science / <i>Richard Rubin and Thomas J. Froehlich</i>	1469
Ethical Issues in Information Systems / <i>Vladimir Zwass</i>	1484
Ethiopia: Libraries, Archives, and Museums / <i>Shiferaw Assefa</i>	1494
Everyday Life Information Seeking / <i>Reijo Savolainen</i>	1506
Evidence-Based Practice / <i>Prudence W. Dalrymple</i>	1516
Exhibition Design / <i>Lee H. Skolnick, Dan Marwit and Jo Ann Secor</i>	1523
Facet Analysis [ELIS Classic] / <i>Douglas J. Foskett</i>	1534
Faceted Application of Subject Terminology (FAST) / <i>Eric R. Childress and Diane Vizine-Goetz</i>	1539
Federal Electronic Information in the United States / <i>Carol D. Doyle</i>	1549
Film and Broadcast Archives / <i>Karen F. Gracy and Karen E. King</i>	1560
Film Archiving: History / <i>Steve Ricci</i>	1584
France: Archives, Museums, and Libraries / <i>Martine Poulain</i>	1589

Volume III (*cont'd.*)

Functional Requirements for Subject Authority Data (FRSAD): Conceptual Model / <i>Marcia Lei Zeng, Athena Salaba and Maja Žumer</i>	1606
Fuzzy Set Theory / <i>Donald Kraft, Gloria Bordogna and Gabriella Pasi</i>	1618
Games and Gaming / <i>Diane Robson and Breanne A. Kirsch</i>	1636
Genealogical Literature and Its Users / <i>Mavis B. Molto</i>	1644
Genre Theory and Research / <i>Catherine F. Schryer</i>	1662
Geographic Information Systems (GIS) / <i>Timothy F. Leslie and Nigel M. Waters</i>	1671
Geographical Literature: History [ELIS Classic] / <i>Nora T. Corley</i>	1683
Germany: Libraries, Archives, and Museums / <i>Claudia Lux</i>	1693
Global Open Knowledgebase / <i>Kristen Wilson</i>	1710
Government Documents: Collection and Management / <i>Aimée C. Quinn, Lori Smith and James Church</i>	1715
Greece: Archives / <i>Nestor Bamidis</i>	1728

Introduction to the Encyclopedia of Library and Information Sciences, Fourth Edition

How to Use This Encyclopedia

Entries are arranged alphabetically in this encyclopedia (see end papers for alphabetical list). The editors of this edition (ELIS-4) have decided to forego the Topical Table of Contents that was provided in ELIS-3 by editors Marcia Bates and Mary Niles Maack. At the time of publication of ELIS-3, the Topical TOC was crucial for readers to get a sense of how subjects were grouped and an understanding of the field or subfield through the clustering of categorical entries in the print edition. ELIS-4 is envisioned as a primarily online reference work where a Topical TOC does not serve the same purpose. The print edition is served well by the main TOC as well as the detailed index, while entries in the online version are easily discoverable through title, author, keyword, and full text searches.

In sum, relevant entries can be found by

1. Entry title (alphabetical arrangement of entries in the encyclopedia or listing in the end papers)
2. Specific name or keyword, including the index at the end of each volume

If the first name or keyword searched is not found, try several more variations—either different words or a different order of words. Most topics are described in several ways in the literature of a discipline, and the first term or phrase that comes to mind may not be the one used here.

Scope of the Encyclopedia

The title of the third edition, *Encyclopedia of Library and Information Sciences*, ended with the letter “s” because the encyclopedia was broadened to cover a spectrum of related and newly emerging information disciplines, including archival science, document theory, informatics, and records management, among others. The fourth edition continues this trend but with an extensive focus on the aspects of library and information sciences that have been heavily impacted by the adoption and reliance on online information distribution. This focus is reflected in the inclusion of numerous new entries such as digital preservation, altmetrics, web-scale discovery services, demand-driven acquisitions, and global open knowledgebases. Alongside these entries based on entirely new topics, the expanded use of the Internet for information has led to new treatment of traditional LIS topics such as resource description and access (RDA) that reflects the adoption of new standards for cataloging.

ELIS-4 also seeks to build upon the description of professional practice to round out the theoretical perspective that previous editions covered very well. Both current editors are academic research librarians and thus, focused heavily on addressing gaps in the encyclopedia related to academic research information while still relying heavily on the structure established by editors of ELIS-3. For example, ELIS-3 introduced country profiles and ELIS-4 builds upon that with new entries for New Zealand and a third on Brazil, in addition to revisions for Slovakia, Netherlands, Canada, Belarus, Kazakhstan, and Brazil among others. This edition also expands the number of entries for named cultural and information entities that did not appear in previous editions, such as the National Library of Medicine, North American Serials Interest Group (NASIG), the International Association of Scientific, Technical and Medical Publishers (STM), and ASLIB, as well as entities like the HathiTrust that have been established since the last edition was published. A number of new entries describing important information conferences such as the Acquisitions Institute at Timberline, the Charleston Conference, and Electronic Resources in Libraries (ER&L) also help round out the encyclopedia and further the description of the current state of academic research librarianship.

ELIS-4 also continues the tradition of designating important entries of historical or theoretical importance as “ELIS Classics.” These are entries by major figures in the library and information sciences or those that describe core concepts in LIS theory, practice, or education that appeared in earlier editions of the encyclopedia. The current editors preserved the approximately 40 previous “ELIS Classics” and designated 13 previous entries as new “ELIS Classics.”

There are more than 550 entries, of which more than 20 are new, another 93 are revisions to prior entries that have been brought up to date by their authors or by new authors, about 30 are ELIS Classics, and about 400 are reprinted from an earlier edition since they have remained relevant to the present. It is important to note that the editors also had to make some choices related to retiring entries that were no longer relevant—due to the passage of time and the development of the field, the technologies and theories described in those entries were deemed to be out of scope for the new edition and thus not revised or reprinted.

Encyclopedia Authors

As in past editions, the authors writing for the encyclopedia are major researchers, librarians and practitioners, and leaders in the fields and subfields in the disciplines in which they are writing. Noted scholars are well represented, and a number of authors are former leaders in LIS associations, including the American Library Association (ALA), the Association for College and Research Libraries (ACRL), the International Federation of Library Associations and Institutions (IFLA), the American Society for Information Science and Technology (ASIS&T), and the American Association of Library and Information Science Education (ALISE). In addition, there are many contributors who are current or former directors of major institutions. As in past editions, the editors are very proud of the range and diversity of authors who have written these entries for the encyclopedia and we thank them for sharing their expertise with the current and future readers and researchers in the field.

Finally, the editors for ELIS-4 have grappled with the challenges of entry generation that was noted by previous editors in nearly every edition: that not all ideas, topics, and potential entries were able to be completed for publication in this edition. While we made a valiant attempt to include entries identified by ELIS-3 editors but not secured for publication in that edition, we sometimes could not find authors willing to take those topics on. Similarly, we were sometimes unable to secure revisions to entries from new authors when previous authors were unable to perform that task. To the greatest extent possible, we endeavored to replace authors when entries were deemed important enough to appear in ELIS-4 but initial or previous authors had to decline or defaulted. No doubt, the editors of ELIS-5 will also pick up the mantle and attempt to round out the encyclopedia with entries for anything that ELIS-4 missed. As noted by editors Bates and Niles Maack in ELIS-3, this problem of missing topics was also acknowledged by Allen Kent, editor of the first edition of ELIS. Kent stated in 1973, "I have prepared this presentation to make sure the lessons of Diderot-d'Alembert are recalled in terms of encyclopedia-making as an exercise in the art of the possible."

Background and Development of the Encyclopedia

The first edition of ELIS, under the editorship principally of Allen Kent and Harold Lancour, was published between 1968 and 1982. The 33 volumes of the first edition were published in alphabetical sequence during those years. After the "Z" volume appeared in 1982, a number of supplements were published at roughly the rate of two per year, up to and including volume 73, which appeared in 2003. Miriam Drake was appointed editor for the second edition, which appeared in 2003, both online and in paper. The second edition came out at one time in four large-format volumes, with a supplement in 2005 [3]. Kent and Lancour covered a wide range of librarianship, information science, and some computer science topics. Drake, an academic library director, emphasized academic libraries, and the ELIS-2 volumes contained many profiles of major academic libraries and professional library associations.

The third edition, under the editorship of Marcia Bates and Mary Niles Maack, reflected a growing convergence among the several disciplines that concern themselves with information and the cultural record. As information science educators and noted researchers in the field, their focus was on growing the encyclopedia in the theoretical fields of information sciences as well as drawing together the associated information and cultural disciplines such as archival sciences and museum studies within the overall field of LIS.

For this edition, we have focused on developing the encyclopedia to reflect the changing nature of information production and consumption through online and digital forms. We have also endeavored to fill in gaps in the description of important people, places, and theories in the information sciences, and further enhanced the description of important concepts related to the provision of research information and the field's major institutions.

We continue to see the audience for the encyclopedia just as previous editors have: as principally consisting of 1) the educated lay person interested in one or more of its topics, 2) students learning about a topic, and 3) professionals and researchers in the several fields who want to learn about something new, or to be refreshed on a familiar topic.

We honored the previous editors by reengaging their superb Editorial Advisory Board with significant new additions of experts known to the current editors. (See listing in the front matter.) These leaders and experts from as many disciplines as are in the encyclopedia provided excellent guidance and feedback for the editors as they began the process of new topic generation, evaluation of previous entries, and offering to author or review numerous entries throughout the process of publication.

All new and revised entries were reviewed by one or more outside expert reviewer as well as one or more of the editors. Referees provided invaluable feedback to authors, including noting errors or omissions as well as making suggestions on additional aspects of the topic to cover. While we made every reasonable attempt through this process to check the accuracy of every entry and every fact, undoubtedly readers will find some topics explained more thoroughly or accurately than others. Indeed, due to the time frame from the beginning of the generation of the fourth edition and the time of publication, readers will reasonably note that some topics have been quickly superseded due to this passage of time, so the

date of acceptance of the entry will be noted on each entry since several years may have passed since the writing of the entry and the publication of this edition.

Acknowledgments

This edition of the encyclopedia was possible only through the countless hours that the editors, John McDonald and Michael Levine-Clark, spent reviewing the previous encyclopedia entries, outlining the topics that were missing or that were newly emerging in the field, and identifying appropriate expert authors to write those new entries. In addition, the editors devoted extensive time to corresponding with previous authors encouraging them to revise their entries, and finding replacement authors for important entries that needed revisions but whose original authors were unavailable.

Both editors wish to acknowledge the expertise of each other and their knowledge of our field, their extensive network of contacts, and their ability to work closely together to ensure the success of this encyclopedia. Neither of them could have completed this project alone.

They acknowledge and thank the Taylor & Francis Group editors, Claire Miller and Rich O'Hanley, as well as Susan Lee, who passed away at the early stages of the preparation of this edition, and more recently, Alexandra Torres, who supported and kept the editors and authors on track over the course of the years of work on this edition of the encyclopedia.

The editors thank the authors who wrote and revised entries, and the huge number of reviewers who refereed the entries. Without their dedication, expertise, and willingness to share their knowledge with others, there would be no encyclopedia. They also wish to thank the Editorial Advisory Board for their advice, suggestions of topics and authors, their hours spent writing or reviewing for the final edition. They also wish to thank the previous editors, Marcia Bates and Mary Niles Maack, whose organization and structure for ELIS-3 provided an excellent blueprint for ELIS-4.

Information Retrieval Protocols: Z39.50 and Search and Retrieve via URL

William Moen

Texas Center for Digital Knowledge, University of North Texas, Denton, Texas, U.S.A.

Abstract

Information retrieval (IR) protocols support effective and interoperable intersystem search and retrieval. Although intersystem search methods have been envisioned and under development since the 1970s, it was the Z39.50 IR protocol, first released in 1988, that demonstrated real-world possibilities for such search and retrieval. As the networked information environment changed with the emergence of the World Wide Web, the need for standard IR protocols did not disappear, and one can argue the need is even more compelling given both the visible and invisible Web. A new protocol, based on the experience from Z39.50 but simpler and more comprehensible than Z39.50, is now being used for Web search and retrieval. Search and retrieve via URL (SRU) uses Web technologies and standards resulting in a Web friendly protocol that provides standard search access to existing Z39.50 resources and a wide-range of new non-catalog digital resources. This entry provides both an overview of the two protocols and technical details to understand both. A brief discussion of IR and communications protocols provides background to the specifics of these two IR protocols. Although communication protocols are by their nature technical specifications, this entry focuses on an overview of the functions and capabilities of the protocols. It uses technical concepts and terminology from the protocols to help explain how the protocols work but limits discussion of technical details.

INTRODUCTION

In the 1970s, a number of library leaders, such as Henriette Avram at the Library of Congress and the developer of the machine-readable catalog record (MARC), envisioned the convergence of computing and telecommunications that would enable machine-to-machine communication for accessing bibliographic and other types of information. Initial work on intersystem communication focused on connecting large bibliographic databases such as those at the Library of Congress, the Online Computer Library Center (OCLC), and the Research Libraries Group (RLG). Making this vision a reality required the development of standard protocols for intersystem communication. Protocols specify rules for communication including what information can be exchanged, in what format, and in what order. Thirty years later, the networked information landscape has changed dramatically, but the need still remains for standard protocols that support information retrieval (IR) transactions (e.g., sending a query and receiving the results of the executed query) against a range of databases or systems. Standards development work through the 1980s and 1990s yielded the ANSI/NISO Z39.50 IR Protocol, developed in a historical context predating the World Wide Web. By the late 1990s, Web technologies were providing a new context for networked IR, and implementors of Z39.50 and others responded to these changes by evolving Z39.50 into Search and retrieve via URL (SRU), a protocol that uses key Web standards and technologies.

This entry addresses both Z39.50 and SRU. A brief discussion of IR and communications protocols provides background to the specifics of these two IR protocols. Although communications protocols are by their nature technical specifications, this entry focuses on an overview of the functions and capabilities of the protocols. It uses technical concepts and terminology from the protocols to help explain how the protocols work but limits discussion of technical details.

IR

IR, in the context of protocols, can be viewed very simply or quite complexly. At its simplest, IR involves issuing a query to an IR system, having the IR system execute the query, and presenting the results of the query to the user (human or machine). Web search engines such as Google provide exactly this functionality. The vision for networked IR assumes, though, an environment that contains a large number of IR systems and their databases that provide a range of search and retrieval functionality but differing in important ways (e.g., types of field searching supported).

A first step in preparing a protocol to support IR transactions requires modeling those transactions and the components of IR systems. Fig. 1 illustrates these basic components of the IR model.

The following description provides an abstract view of IR and IR systems in the context of bibliographic

Fig. 1 Abstract model of IR.

databases (i.e., databases containing metadata records describing bibliographic items held, for example, in a library's collection). This description of an abstract model for information retrieval is derived from *ANSI/NISO Z39.89-2003. The U.S. National Z39.50 Profile for Library Applications*. The author drafted the text describing the abstract model in his capacity as chair of NISO Standards Committee AV that created this profile. Since this is an abstract view, actual implementation of these components may differ.

- **Bibliographic database:** This is the logical component that stores data representing bibliographic items. These representations can be created according to accepted standards (e.g., the Anglo-American Cataloguing Rules) and can reflect the use of various metadata element sets (e.g., MARC 21, Dublin Core, or others). Typically, the database records include information about the title, author, subject, and other salient features of bibliographic items. The physical structure of the database will be implementation specific, and no specific physical database model is assumed (e.g., relational, flat file, etc.).
- **Access points and indexes:** This is the logical component related to searching the database. This model assumes there is an index, which is a list of values with pointers to the database records that contain those values. Indexes are created for specific types of searches the IR system will support, and reflect searchable areas of the database record. A bibliographic database in an online catalog implementation typically supports title, author, subject, and other types of searches. The physical structure of an index and how it associates the

list of values with pointers to database records will be system and implementation specific.

- **IR system:** This is the logical component that manages the search of the database and retrieval of records from the database. It typically provides an interface to receive a query and then executes the query by matching the search criteria with information stored in the indexes. When values in the index(es) match the query criteria, the system retrieves the relevant records from the bibliographic database for presentation to the user.
- **Query:** This is the logical component that contains simple or complex criteria along with a search term specified by the user (human or machine). Also referred to as search criteria, the query can contain criteria related to access points to be searched (e.g., search the author access point), characterizations of the search term (e.g., treat this search term as a phrase or treat this search term as a date), and also indicate processing of the search term (e.g., perform right truncation where specified).
- **Result Set and retrieved records:** This logical component manages the results of the executed query. The result set comprises all records that the IR system identified as matching the criteria contained in the query. From this Result Set, the IR system selects one or more records to return to the user. A specific IR system may store the Result Set for later processing, but that consideration is implementation specific and not addressed by this model.

IR can include other tasks beyond what the basic model describes. For example, some IR systems allow the user to specify how the results should be sorted (e.g., by date of publication in ascending order). Protocol developers face the challenge of modeling all IR transactions and components in a way that a standard IR protocol does not privilege specific implementations or structures. Before discussing the details of Z39.50, a basic description and explanation of a protocol is needed.

COMMUNICATIONS PROTOCOLS

Protocols governing communication and behavior between two entities exist for human-to-human as well and machine-to-machine interactions. For example, diplomatic protocols guide the interaction between representatives of sovereign entities. The protocols are agreed upon rules (written or unwritten) for governing behavior. When addressing machine communication, the rules must be specific and well-documented to ensure machine-to-machine communication is successful and the machines and applications behave according to the rules.

Machine-to-machine communication typically involves the sending and receiving of messages. One machine or an

application residing on the machine (referred to here as the client) initiates the communication by sending a message requesting some service or other behavior from the receiving machine or application on that machine (referred to here as the server). The server responds by returning a message to the client. The model for this communication is characterized as request and response.

A communications protocol defines the services supported and provides the rules controlling the order in which messages can be sent, the contents of those messages, allowable request and response messages, and other aspects of the communication (e.g., the character set for encoding the data in a message). Machines conforming to the protocol can conduct successful intersystem communication because they know how to send and receive protocol messages and “understand” the content of those messages.

In the networked information environment of computers and their applications, there are a range of familiar communications protocols such as File Transfer Protocol (FTP), Simple Mail Transport Protocol (SMTP), and HyperText Transfer Protocol (HTTP) to name a few. Each is distinguished by the services or functions it provides. In fact, a large number of protocols exist to support successful communication between two machines and applications. Models representing a layering approach to intersystem communication (e.g., in the Open Systems Interconnection (OSI) seven-layer model and the five-layer model from the Internet) identify specific protocols to handle communication from the lowest layer of physical connection through routing and session information to the top layer, which in both models is called the application layer. Z39.50 is an application-layer protocol as indicated by the title of the Z39.50 standard: *Information Retrieval (Z39.50): Application Service Definition and Protocol Specification*.^[1]

Returning to the context of IR protocols, the following are basic aspects that such a protocol needs to accommodate:

- Providing a standard way to encode the request and response messages
- Specifying methods to transport request and response messages across a network
- Identifying a database on a server to search
- Utilizing a vocabulary and grammar for expressing search requests, search criteria, retrieval requests, etc.
- Specifying formats for records that are returned in response to a search request.

The Z39.50 protocol provides these and more, which are discussed next.

THE Z39.50 IR PROTOCOL

Z39.50 is a technical standard, developed under the auspices of the National Information Standards Organization

(NISO), a standards developer accredited by the American National Standards Institute (ANSI). At the international level, Technical Committee 46 of the International Organization for Standardization (ISO) worked concurrently on an IR protocol called Search and Retrieve. This section provides a brief history of the development of the Z39.50 standard, explains in relatively nontechnical terms what the standard addresses, and discusses sufficient details of the specifications to yield a basic understanding. Many resources are available that discuss the Z39.50 protocol, features, and implementations (see Bibliography).

A Brief Chronology of Z39.50 Development

The nearly 30-year period during which Z39.50 and SRU, its successor protocol, were developed was marked by major computing and networking technology changes that strongly influenced the character of these IR protocols. Technical standards often reflect assumptions and beliefs about existing technologies, and it is fair to say that this was true for Z39.50.

The genesis for the standard was the late 1960s and early 1970s when library leaders began envisioning a future of interconnected automated bibliographic systems and identified the need for computer communication protocols that would enable the interconnection of systems and sharing of bibliographic data. The need for an IR protocol emerged also from visions for a national bibliographic network articulated by library leaders such as Henriette Avram and organizations such as the Library of Congress and its Network Advisory Committee, the National Commission on Library and Information Science, and the Council of Library Resources. A detailed historical treatment is beyond this entry's scope, but readers interested in Z39.50 history can review chapter 4 in *The Development of ANSI/NISO Z39.50: A Case Study in Standards Evolution*.^[2]

Work on the Z39.50 standard began in 1979 by a formal standards committee authorized by NISO. NISO issued the first version of the standard in 1988.^[3] After 1988, work on protocol development shifted from NISO, which disbanded the standards committee, to a group of people and organizations interested in implementing the standard. This group became known as the Z39.50 Implementors Group (ZIG). NISO established the Z39.50 Maintenance Agency, located at the Library of Congress, to oversee further development of the standard. The Maintenance Agency and the ZIG worked collaboratively to produce a revision to the 1988 standard, which was submitted and approved by NISO in 1992.^[4] One specific goal of the 1992 standard, known as Version 2, was to harmonize the Z39.50 specifications with those in the ISO Search and Retrieve standard. Version 2 also specified critical services lacking from the 1988 standard such as access control, and as a result it provided a solid basis for widespread pilot projects, testing, and production implementations by members of the ZIG.

The early versions of the protocol were particularly library-centric, in that many of the specifications addressed issues related to searching bibliographic databases in the context of library catalogs. ZIG members, however, wanted to evolve Z39.50 into a more generalized IR protocol that could be used by libraries and many other information providers. Version 3 was approved in 1995 by NISO.^[5] Many new features were specified in Version 3, and it became the basis for wide-spread implementation, albeit predominantly within the library community and by information services supporting libraries. In addition, the separate ISO Search and Retrieve standard was abandoned, and in its place, ISO adopted verbatim the 1995 Z39.50 standard and labeled it ISO 23950-1998.

Part of NISO's standards development process as approved by ANSI includes regular 5 year reviews of published standards. In the late 1990s, the Maintenance Agency initiated this review and issued in 2003, a revised version of the Z39.50 standard.^[6] The Maintenance Agency viewed this version as a reaffirmation version, and included clarifications, commentaries, defect reports, amendments, and implementor agreements.

Z39.50 Protocol Details

When discussing Z39.50, it is important to distinguish between: (1) the technical standard that defines the protocol; and (2) the implementation of those specifications in software. Taking the latter first, system developers (e.g., vendors of integrated library systems) implement the protocol specifications in software programs: client-side software and server-side software. The Z39.50 client initiates a communication session with the Z39.50 server. A user (human or machine) initiates a search, which is passed to the Z39.50 client for processing into standard protocol messages and sends the query to the Z39.50 server. The Z39.50 server passes the request to a local IR system, which executes the search, finds records that match the criteria, and then returns results back to the Z39.50 client via the protocol. The Z39.50 client passes the results back to the local machine for presentation to the user. Building on the IR model presented earlier, Fig. 2 illustrates where the Z39.50 client and server software logically sit in relation to the client- and server-side applications.

The Z39.50 client and Z39.50 server each have their own responsibilities, listed below in the order of a typical Z39.50 session:

- Initiate a session: client
- Send query: client
- Execute query: server
- Create result set: server
- Request records "in" result set: client
- Specify database elements to be returned: client
- Specify format in which to return records: client
- Create retrieval records and sent to client: server

Fig. 2 Z39.50 and the abstract model of IR.

As a communications protocol, Z39.50 specifies a standard set of messages that are communicated between two systems. The initiating system's request needs to be transformed from the local language of that system into the language of Z39.50. The Z39.50 client and server both understand the meaning of the Z39.50 language, and thus provide the communication link between the two different systems. Upon receipt of the Z39.50 message, the Z39.50 server then translates it into the local language of the IR system. For example, it maps a request for a title search where the search term is a phrase into the appropriate commands, syntax, and query of the local IR system.

In the context of the protocol specifications, Z39.50 defines a set of "services." A Z39.50 service describes functionality and defines the specific protocol messages related to that service exchanged between the Z39.50 client and Z39.50 server in support of that functionality. Z39.50 defines 14 services, but for purposes here, only a few core services will be discussed: Init, Search, and Present. These services enable: (1) establishing a connection between a client and server (Init); (2) issuing a query (Search); and (3) retrieving results (Present).

Init service

The Init service provides for a Z39.50 client to initiate a connection and session with a Z39.50 server by first issuing an Init request message. Included in the structured message are a number of parameters: Version, Id/authentication, Options, Preferred-message-size, Exceptional-record-size, Implementation-id; some of these are mandatory and some are optional. The Z39.50 client sends the Init request message with values listed for each of the parameters. The Z39.50 server responds by returning to the Z39.50 client an Init response message with the following parameters (again, some of which are mandatory and some optional): Version, Id/authentication, Options, Preferred-message-size, Exceptional-record-size, Result, Implementation-id. If the server responds positively to the Init request, it returns a value of "accept" in the result parameter. Upon

successful negotiation in the Init service, the client can then move to requesting the server to execute a search using the Search service.

Search service

For successful IR interoperability between two systems, there are two important considerations: a mutual understanding of the search request and a mutual understanding of the format of records retrieved. We will examine how Z39.50 addresses these two requirements, since at its core, Z39.50 was developed to support interoperable search and retrieve.

When one submits a search to a local IR system via its native interface, there is a tight linkage between the search interface offered to the user and the underlying IR system and database. Communication is not an issue. Yet, to send a search from one system to a different IR system, the search must be transformed into a language understood by both systems where information about some of the following must be clearly communicated:

- The database to search.
- The access points or searchable fields to search.
- How search terms are to be interpreted, such as treating the search term as a word, phrase, date, normalized name, etc.
- The use of Boolean operators for complex queries.
- Other search qualifications and criteria, such as limiting the search by date, language, etc.

Z39.50 defines a standard language for expressing searches. The language is very rich and precise to reduce ambiguity in the communication. A query in Z39.50 is a specified structure for expressing the search requirements; it identifies a database to search and characterizes the search term using attribute types and values. A query can also include Boolean operators.

Key to the query is the attribute types and their values; these are what allow the search to be expressed in a standardized and mutually understood vocabulary and grammar. The following is an example of part of a Z39.50 query:

(1,1003)(2,3)(3,1)(4,1)(5,100)(6,3) Twain, Mark

The pairs of number in parentheses are the attribute/type value pairs and “Twain, Mark” is the search term. The following explains how the attribute types and values characterize the query term, “Twain, Mark.”

Attributes and their permissible values are defined in attribute sets. A basic Z39.50-related attribute set goes by the label of Bib-1 (for use when searching a variety of databases).^[7] The Bib-1 attribute set defines six attribute types (identified by the first number in parentheses): Use (1); Relation (2); Position (3); Structure (4); Truncation (5); and Completeness (6). The Z39.50 query contains a number representing an attribute as the first part of the

type/value pair. The use of numbers avoids problems of words in various languages and yields more universality.

Each attribute type represents a feature of the search and search term; for example the Use attribute indicates the index to be searched, while the Relation attribute indicates, for example, that the search term should match exactly an entry in the index, and the Truncation attribute indicates whether the IR system should perform some type of truncation on the search term. The Bib-1 attribute set defines the values associated for each attribute type. For example, if the Use attribute value is 1003, this means that the IR system should process this query as an author search; if the value is 4, the IR system should process the query as a title search. It is beyond the scope of this entry to give all the details on attribute types and values, but this indicates how the search term can be characterized using a standard vocabulary and grammar to result in intersystem communication for the purpose of searching.

Parsing the Z39.50 query listed earlier, which means in human terms “search for items where Mark Twain is listed as author,” the use of attribute type/value pairs are understood by the server as:

- (1,1003) means execute this search as an author search.
- (2,3) means exactly match the search term with an entry in the index.
- (3,1) means to begin matching the search term with the first term in the field.
- (4,1) means to treat the search term as a phrase rather than two words.
- (5,100) means to carry out no truncation on the search term.
- (6,3) means that the search term should match the complete data value in the field (i.e., the entry in the index).

The Z39.50 server receives the query as expressed in the type/value pairs, parses the query, and maps the search to the local IR system and its search engine.

Present service

The other aspect of IR is the return of records to the Z39.50 client that match the query. The Z39.50 Present service is used to request records to be returned from the result set, how many to return, what syntax the records should be returned in, and what elements in the records to return. To support interoperability, Z39.50 registers a number of record syntaxes in which records can be exchanged between Z39.50 clients and servers. The original focus of Z39.50 was on bibliographic records and the retrieval of MARC records. As Z39.50 evolved into a general IR protocol, the MARC format for records became just one of a variety of record syntaxes in which records could be formatted and returned via Z39.50. Record syntaxes include HTML, Extensible Markup Language (XML),

and others, including a syntax developed by the ZIG called Generic Record Syntax (GRS).^[8] While accommodating more applications with this variety of record syntaxes, interoperability problems also increased.

This brief glimpse into some of the details of Z39.50 illustrates that for intersystem communication to occur, the Z39.50 client and server must not only support the defined protocol messages but also understand the language of Z39.50, its vocabulary and grammar. Most current Z39.50 implementations robustly support the protocol messages. However, implementors make choices from the options available in the standard for specific protocol messages. Also, the local IR system on the Z39.50 server side does not always provide the functionality requested by the Z39.50 client as expressed in protocol messages. These and other issues have led to interoperability problems. There has been, unfortunately, a pervasive sense that Z39.50 did not live up to the promises of providing a solution for interoperable intersystem search and retrieval across disparate databases.

INTEROPERABILITY AND INTERSYSTEM IR

Implementing a standard IR protocol on systems is intended to enable interoperability of those systems and applications. System-level interoperability can be defined as the ability of two or more systems or components to exchange information and use the exchanged information without special effort on either system. One can also define interoperability from the perspective of the end user in terms of the user's ability to successfully search and retrieve information in a meaningful way and have confidence in the results. Interoperability between two systems can be assessed from a binary perspective; they either do or do not interoperate. However, experience has demonstrated that when two systems have implemented the Z39.50 protocol, it is more likely that systems may be more or less interoperable, and interoperability is better assessed as a continuum rather than a binary decision. This raises the question of what acceptable levels of interoperability can be produced, especially from the perspective of the end user.

To understand how or why IR systems may not interoperate or not have an acceptable level of interoperability, a number of factors that threaten interoperability can be identified:

- Multiple and disparate systems, operating systems, IR systems, etc.
- Multiple protocols such as Z39.50, HTTP, SOAP, etc.
- Multiple data formats, syntax, metadata schemes such as MARC 21, UNIMARC, XML, ISBD/AACR2-based metadata, Dublin Core, etc.
- Multiple vocabularies, ontologies, disciplines such as LCSH, MESH, and AAT.

- Multiple languages, multiple character sets.
- Indexing, word normalization, and word extraction policies.

If a protocol has a range of options, implementors can choose from (e.g., what protocol services are implemented, specific values for parameters, etc.) as is the case with Z39.50, different implementations of the protocol specifications can threaten interoperability. However, the experience with Z39.50 has shown that the key threats to interoperability relate mostly to differences in local IR systems specifically the differences in search functions supported, the indexes available for searching, and the record syntaxes supported for retrieved records. Examples of these differences include whether IR systems support the searches being requested by the client, such as how to treat the search term (e.g., as word, phrase, date, etc.), the access points to be searched (e.g., author, title, subject, ISBN, etc.), and the format of records available (e.g., in MARC, MARCXML, etc.)

Optimal interoperability occurs not only if the Z39.50 client and server both implement the same protocol services and choices among options within the protocol but also when the IR system on the Z39.50 server side provides the search functions requested by the Z39.50 client, including types of searches and access points, and also is able to supply the records in the syntax requested by the Z39.50 client.

A common approach to address the threats to Z39.50 interoperability was the development of application profiles. A profile specified what Z39.50 clients and servers had to implement from the options available in the Z39.50 standard, as well as the searches supported on the local IR system. Conformance to a profile's specifications increased the level of interoperability. An example of such a profile is *The U.S. National Z39.50 Profile for Library Applications* published by the NISO as ANSI/NISO Z39.89.^[1]

A NEXT GENERATION Z39.50

The development of Z39.50 and release of Version 3 in 1995 occurred in advance of the emergence of the World Wide Web in the 1990s. By the late 1990s, the ZIG was discussing how the broader Web community, and especially those involved with Web search, could be made interested in the power provided by the Z39.50 IR protocol. Yet, where the ZIG saw Z39.50's power, many in the Web community and even some in the library community—its core implementation context—perceived it as difficult and complex, heavyweight, reflecting old technology, not Web friendly, and in some cases simply broken. The ZIG recognized that the Web was quickly becoming the common implementation environment. For several years Z39.50 implementors discussed and tried out a

number of initiatives as part of a Z39.50 International Next Generation (ZING) project.^[9]

A pivotal meeting of the ZIG occurred in 2001 at which a discussion about the future of Z39.50 resulted in a consensus recognition that Z39.50 needed to evolve in the context of the Web. The goal for developing the next generation Z39.50 was to lower the barriers to implementation while preserving the intellectual contributions of Z39.50 and discarding those aspects no longer useful or meaningful. Part of lowering the barrier to implementation was to recast Z39.50 protocol specifications in terms of existing and emerging Web technologies, tools, and standards (e.g., HTTP, XML, and XML schemas). Part of preserving the intellectual contributions of Z39.50 was to separate the abstract and semantic models provided in Z39.50 from representation of the protocol in the arcane Abstract Syntax Notation (ASN.1) and associated Basic Encoding Rules (BER) and running it directly over TCP/IP for transport rather than HTTP.

In 2001, an international team of implementors and standards developers began work on a new IR protocol that would be simpler, more easily implemented, and more comprehensible than Z39.50 and most importantly Web compatible. The result of discussions and deliberations was the decision to develop a new Web services based protocol: SRU. The name of the new protocol has changed since its inception in 2001. Initially it was referred to as Search/Retrieve Web Service (SRW). This was later accompanied by SRU. Except for the method the client used for sending a search request to the server, the details of the protocol were the same. By 2007, the label SRW had been deprecated and the protocol is officially known as SRU. The first version of the protocol was released in late 2002; Version 1.1 was released in 2004, which was registered with NISO. The current Version 1.2 was published in 2007.^[10]

The Z39.50 Maintenance Agency at the Library of Congress plays a key role in managing the development of the new protocol and now serves as the maintenance agency and managing editor for SRU, supported by a SRU Editorial Board consisting of the managing editor along with a senior editor, XML editor, and associate editors. The Board oversees the development of proposals for changes and enhancements, and a SRU Implementors Group, an open membership group, serves in an advisory capacity to the Editorial Board.

SRW

SRU addresses the same IR problems confronted by Z39.50, namely, communicating with a range of information services and servers that have their own local IR systems with different database structures, indexes, and local query structures. However, SRU adopts current standards for syntax of messages and records (i.e., XML)

Fig. 3 SRW Communication using SOAP.

exchanged between a client and server and for transport of the messages (i.e., HTTP). It retains and builds on the abstract models, concepts, and functions developed through the experience with Z39.50 such as abstract access points, abstract record schemas, result sets, and others. The protocol defines a set of operations and associated parameters (see below) and all responses are encoded in XML. The Contextual Query Language (CQL) is used to represent queries in search requests (see below). The result is a Web friendly and standard protocol for networked IR.

At the outset of protocol development, there were two related protocols referred to as SRW and SRU. In fact, there is no real difference between SRW and SRU at the protocol parameter level but only in the way they are implemented as Web services.

The basic difference between them relate to how they issue search requests. SRW uses SOAP (originally known as Simple Object Access Protocol) and encodes messages in XML within SOAP (Fig. 3). SRU uses the Representational State Transfer (REST) approach, which encodes protocol messages from the client in the URL syntax and issues a HTTP GET request (Fig. 4). Both protocols return data encoded in XML, and both use HTTP for transport of messages.^[11]

Protocol Operations and Examples

SRU uses the concept of “operation types” to describe and define what IR functions the protocol supports and defines the following operations:

- *searchRetrieve*: Expresses the query criteria and specifications for records to be returned
- *Explain*: Allows a client to retrieve a description of the facilities available at a server
- *Scan*: Allows the client to request a range of the available terms at a given point within a list of indexed terms

Fig. 4 SRU Communication using HTTP GET.

The searchRetrieve and explain operations are core to the protocol, and each is discussed in more detail below.

searchRetrieve operation

This operation combines the Z39.50 Search and Present services in one operation. The searchRetrieveRequest message contains the query which is expressed using CQL (see below). In addition to the query, the searchRetrieveRequest contains specifications for returning the records that match the query, such as what schema should be used to package the retrieved records.

If one uses SRW, the searchRetrieveRequest message is encoded in XML and sent via HTTP wrapped in SOAP. Fig. 5 is part of a searchRetrieveRequest (in XML) that includes a single-word query.

There are a number of parameters defined for the searchRetrieveRequest, and Fig. 5 shows two mandatory parameters (<version> to indicate the version of the protocol; <query> to express the search criteria), and several optional parameters (<maximumRecords> to indicate how many records should be returned; <startRecord> to indicate in the list of records found where to begin returning; and <recordSchema> to indicate in what format the records should be returned. In this sample case, the request is to have the records returned in the form of Dublin Core records according to a Dublin Core XML schema.

```
<searchRetrieveRequest>
  <version>1.1</version>
  <query>texas</query>
  <maximumRecords>1</maximumRecords>
  <startRecord>1</startRecord>
  <recordSchema>dc</recordSchema>
</searchRetrieveRequest>
```

Fig. 5 Sample searchRetrieveRequest expressed in XML.

If one uses SRU, the searchRetrieveRequest parameters are expressed in standard URL syntax, which includes the baseURL for the server separated from the protocol parameters with a question mark (?). Fig. 6 shows the same searchRetrieveRequest as in Fig. 5 but expressed as a URL.

Fig. 6 shows that the URL syntax can express all searchRetrieveRequest parameters without any loss of specification.

After the server receives the searchRetrieveRequest and executes the search and finds records, it returns a searchRetrieveResponse (no matter whether the searchRetrieveRequest was sent via SOAP or as HTTP GET) that indicates the number of records found and may also include the records found. Fig. 7 is a sample of a searchRetrieveResponse to the sample searchRetrieveRequest in Figs. 5 and 6.

There are a number of parameters defined for the searchRetrieveResponse, and Fig. 7 shows two mandatory parameters (<version> ; <numberOfRecords> to indicate the number of records found on the server), and several optional parameters (<records> which indicates the beginning of the records being returned; <record> which indicates the segment containing the records; <recordSchema> which indicates the XML schema according to which the records are encoded; and <recordData> that contains the actual record. In this example, the <schema> parameter indicates that the records are formatted according to the Dublin Core (i.e., DC) schema, as requested in the searchRetrieveRequest above. The <recordData> parameter in this example contains only one DC element simply to illustrate elements that might comprise the record.

In summary, the searchRequestResponse is in XML syntax and may include the actual records found in the XML schema requested by the client. Other schemas in which records can be returned (assuming the server supports those schemas) include ONIX, MODS, and MARCXML.

Explain operation

A challenge for Z39.50 in the context of interoperability was the difficulty for a Z39.50 client to discern what a Z39.50 server supported in terms of Z39.50 services and especially in terms of available access points and record formats. The development of SRU gave priority attention to ensuring a robust method for the server to tell the client what it supports. The explain operation addresses this need. A client sends an explainRequest to the server and the server responds with an explainResponse, and the response message contains a record in XML structured according to the ZeeRex schema.^[12] The ZeeRex record provides several key pieces of information including:

<http://www.loc.gov/z39voy?operation=searchRetrieve&version=1.1&query=texas&recordSchema=dc&startRecord=1&maximumRecords=1>

Fig. 6 Sample searchRetrieveRequest expressed as URL.

- Information about the database such as title and description
- Information about how to search in the database including what indexes exist to search
- Information about the record syntaxes in which records can be returned and what record elements can be returned.

With the information contained in the explainResponse, the client is able to configure searches against the server that are likely to be more successful and request records in specific schemas (e.g., MARCXML, MODS, Dublin Core, etc.) that the server is able to supply. Interoperability can be significantly improved because of this protocol operation.

CQL

In addition to the protocol, another component for successful intersystem IR communication is a standard language to express the query. Based on the experience with Z39.50 and in keeping with the desire to build upon that experience, SRU developers created the CQL.^[13] CQL is a formal language for representing queries to issue to IR systems such as Web indexes, bibliographic catalogs, and museum collection information. It is capable of expressing complex queries and yet can be used for very simple keyword searches. CQL is also human-readable, unlike the query types associated with Z39.50.

A CQL query contains one or more search clauses connected by Boolean operators. A search clause contains at a minimum the search term. A single word in a search clause comprises a perfectly legitimate instance, and this reflects the simplicity available in CQL. It has

the power of expressiveness in that the search clause can indicate a specific index to search, and CQL supports relation and proximity operators as well as masking characters (e.g., to indicate truncation) to express more complex queries.

As a general purpose query language, CQL provides a syntax for expressing the component parts of the query. The basic syntax for a CQL search clause is: [index][relation][search term]. CQL also supports searching by semantics or context and introduced the concept of context sets in relation to indexes; this begins to make the meaning of “contextual” in the name of CQL clearer.^[14] For example, a SRU search to a database can indicate that the index to be searched should be in the context of the Dublin Core element semantics. Individual communities can define their own context set to indicate the semantics of the indexes available. Context sets and individual indexes supported by the server can be listed in the ZeeRex record returned through the explain operation, which assists the client in issuing queries that take advantage of what the server offers. Fig. 8 shows legitimate CQL search clauses from the simplest to more complex.

The examples in Fig. 8 show that <index> and <relation> are optional, and further that <index> can be include a prefix to the index name to indicate that the index is from a specific context set.

Current Status and Plans for SRU

A variety of projects and implementations are using SRU for networked IR.^[15] In some cases, implementations provide a SRU gateway to existing Z39.50 servers, For example, the Library of Congress implemented SRU access to its Z39.50 server and can return records in MARCXML, MODS, and even DC.^[16] The European Library uses SRU as a search gateway to 47 European national libraries from a single interface, thus providing metasearch functionality across those libraries’ resources.^[17] SRU is used in venues

```
<searchRetrieveResponse>
  <version>1.1</version>
  <numberOfRecords>10</numberOfRecords>
  <records>
    <record>
      <recordSchema>info:srw/schema/1/dc-
        v1.1</recordSchema>
      <recordData>
        <dc:record>
          <dc:title>The prediction of subsequent violent
            offenses by the inmates of the Texas
            Department of Corrections </dc:title>
        </dc:record>
      </recordData>
    </record>
  </records>
</searchRetrieveResponse>
```

Fig. 7 Sample searchRetrieveResponse.

Search Clause	Explanation
cat	Simple single word search
cat and dog	Simple two-word Boolean search
“black cat”	Simple two word phrase; quotation marks must be used to indicate that words comprise a phrase
title = cat	Search for term cat in a title index
dc.title = cat	Search for term cat in an index defined in the Dublin core context set

Fig. 8 Sample CQL search clauses.

beyond accessing library catalogs. For example, OCLC has developed a SRU interface to the DSpace digital repository system, allowing a standard search interface to the Lucene indexer used in DSpace repositories.^[18] The NISO Metasearch Initiative has included reviewing SRU as the basis for a metasearch search and retrieval standard.^[19]

In a move to gain formal standards status for SRU, the SRU Editorial Board, with support from the SRU Implementors Group, decided to pursue standardization of a specification based on SRU through the Organization for the Advancement of Structured Information Standards (OASIS) Consortium. Work on that effort began in Summer 2007. The specification has not yet been approved as an OASIS standard, and work is continuing on moving the specification through the OASIS process. Members of the SRU Editorial Board established the OASIS Search Web Services Technical Committee and the Committee's work includes the development of an Abstract Protocol Definition.^[20] An important aspect of the OASIS work is to provide methods for accessing servers that support OpenSearch. The OpenSearch provides a method for describing a search engine's interface to assist clients in automating search Web forms.^[21] The OASIS Committee plans to define application protocol bindings that provides the description (either human-readable or machine-actionable) of a server. A client will be able to access any server that provides such a description, if only it implements the capability to read the description file and interpret the description and based on that description to formulate a request (including a query) and interpret the response.

According to Ray Denenberg, cochair of the OASIS Technical Committee and managing editor for SRU, the plans are for the committee to produce initially two bindings: SRU 1.2 (compatible with the current SRU 1.2 specification) and OpenSearch (compatible with the current OpenSearch 1.1 specifications).^[22] These will be straightforward renderings of the two existing specifications. The committee will follow with a third binding for the planned SRU 2.0, a revised version that will introduce new features into SRU. The committee will also initially produce a draft CQL 1.2 (compatible with the current CQL specifications) and will follow later with CQL 2.0, which will introduce new features into CQL.

CONCLUSION

"Information retrieval, while seemingly simple and obvious when accessing Google, is surprisingly complex."^[16] IR tasks can range from simply submitting a keyword search to a search engine to issuing complex queries simultaneously to multiple and diverse information servers living on the Web. Searching a diverse set of IR systems and the data they hold, and then returning results in useful

formats are made possible through the development and implementation of IR protocols. Z39.50 first explored the complexity of intersystem search and retrieval, and the attendant issues of interoperability. The widespread deployment of Z39.50 servers, primarily in the context of library catalogs, demonstrated the utility of a standard, protocol-based, search and retrieval interface to the diversity of library systems. Cross-database searching, or meta-search, was first explored by using Z39.50 for concurrent access to multiple resources, including but not limited to library catalogs.

Search in the context of the Web presented both challenges and opportunities for Z39.50. On the one hand, that protocol appeared to be both library-centric and not Web friendly, and thus there was little take up of that protocol by the wider Web search community. On the other hand, implementors and developers—primarily from the library community—have built on the experience and intellectual contributions of Z39.50 and evolved Z39.50 into a search/retrieve protocol and an associated query language more in line with the needs and expectations for the Web. SRU uses current standards and technologies to reduce the barriers to implementation and provides a robust IR protocol that effectively supports networked IR.

Abstract

The study of Information Retrieval Support Systems (IRSS) focuses on the next generation retrieval systems and Web search engines. It is an emerging research field driven by the demands, challenges, and opportunities of the fast growing Web. The philosophy of IRSS requires us to go beyond the two basic tasks of browsing and searching provided by current retrieval systems. We must provide the necessary new utilities, tools, and languages that help and support a user to perform multiple tasks in finding useful information and knowledge. In the Web context, IRSS may be viewed as an important type of Web-based systems supporting Web Intelligence (WI). The main objective of this entry is to provide an overview of the study of IRSS, covering the emergence of IRSS, the architecture of IRSS, and implementation-related issues.

INTRODUCTION

With the advances of information and Web technologies, everyone faces a great challenge of information overload. One may feel lost in the overwhelming volume of information, and in many cases misinformation. For example, a scientist can have a real difficulty in keeping up with current research and figuring out what has been done by using Information Retrieval Systems (IRS) and search engines.^[1,2] One is no longer satisfied with retrieval systems that provide limited supports of browsing, navigation, and retrieval. There is a great demand on retrieval systems and search engines with a great variety of new functionalities and supports.^[3]

We can observe a few trends in the new, or latest versions of, retrieval systems and search engines that attempt to address the above-mentioned problems. For example, some recent retrieval systems provide better user interface that allows more user control^[4] in the search process and retrieval-results refinement and reorganization. Some search engines provide more utilities that support user exploration of a collection of information items. There are more domain-specific and narrow-scope search engines that make more effective use of domain knowledge and structures of a collection of information items. In addition, results from machine learning, data mining, intelligent agents, and other fields are being incorporated into retrieval systems and search

engines to increase their performance. However, there is still lack of a commonly agreed label for those research efforts, and there seems to be a need of a framework so that we can study them systematically. The recently proposed notion of Information Retrieval Support Systems (IRSS) may serve this purpose.^[5–7] IRSS may be used as a subsystem of a research support system (RSS).^[7–9] They may also be considered a step toward knowledge retrieval systems (KRS).^[10,11]

By introducing IRSS as a new field of study, we may be able to draw the attention of researchers working on the related topics. Many related, but isolated and scattered studies, techniques, tools, and systems can be unified under an umbrella term of IRSS. The benefits are the convergence of new generation retrieval systems, search engines, and Web services that aim to provide a variety of utilities, tools, and languages to support a user to find what they really need, including data, information, and knowledge.

Three fundamental issues are investigated in this entry. We examine the evolution process of retrieval systems, from data retrieval to information retrieval, and from information retrieval to information retrieval support. We outline the conceptual architecture of IRSS and discuss the basic concepts, characteristics, and functionalities of these types of systems. We comment on implementation issues of IRSS with reference to related fields and suggest a technical foundation based on granular computing. The materials of this entry are based on our preliminary studies.^[5–7]

EMERGENCE OF IRSS

There are several factors that affect the evolution of retrieval systems, namely, the characteristics of information items, the characteristics and demands of users, and available technologies. It can be said that retrieval systems evolve from simple and specific task to intelligent and multiple tasks. We are now entering a stage when IRSS are necessary and technologically feasible.

From Data Retrieval to Information Retrieval

Van Rijsbergen provided a comparative study of data retrieval systems (DRS) and IRS regarding their common features and differences.^[12] Both DRS and IRS focus on storage-and-retrieval functionality, with very limited support for other functionalities.

In traditional DRS, data items can be precisely described by using well-understood representation schemes, and user needs can be formally represented by query languages (e.g., SQL). The model is deterministic in the sense that the relationships between data items and user needs are well and objectively defined and consequently exact match and deductive inference can be used. The intolerance of uncertainty of data retrieval had motivated many researchers to search for generalized data retrieval models, such as fuzzy databases and extended Boolean queries.^[13]

The stringent requirements of data retrieval made it unsuitable for the case of documents storage and retrieval where a collection of natural language documents is involved. Information retrieval was evolved from data retrieval by considering the following issues. Documents and user needs cannot always be precisely described, and their relationships are ill and subjectively defined. The model is nondeterministic in the sense that partial or best match and inductive inference are used. The results of an IRS are typically a list of ranked information items. They are documents or paragraphs containing keywords in queries. One needs to read those documents in order to find the required information. In other words, IRS and search engines are reference systems that indirectly meet the user requirements.

From Information Retrieval to Information Retrieval Support

The limited functionalities of IRS and search engines is insufficient to meet the demands of users in the Web age. IRSS have emerged as the next generation in the evolution of retrieval systems that focus on more supporting functionalities at a higher intelligence level.

The emergence of information retrieval support can be seen from several important trends in the search

community. One of them is the separation of vertical search and horizontal search. While traditional horizontal search deals with general purpose search needs, vertical search handles domain-specific needs. Vertical search^[14] plays a daily-increasing important role on the Web.^[15–18] For example, Google Scholar, CiteSeerX, DBLP, MSRA Libra, etc., are specialized retrieval systems for academic literature search; Amazon, Google product search, Microsoft Live product search, etc., are for product retrieval online; Zoominfo is a vertical search engine for company, people network, and job information. All of these vertical search systems provide various ways to better support specific groups of users in particular domains. Another trend is the study of exploratory search systems for users with insufficient domain and contextual knowledge to formulate effective retrieval queries.^[10,19] Many related workshops and special issues have emerged during these years. They include HCIL SOH 2005 Workshop on Exploratory Search Interfaces, SIGIR 2006 Workshop on Evaluating Exploratory Search Systems, SIGCHI 2007 Workshop on Exploratory Search and Human Computer Interaction, a special issue on “Supporting Exploratory Search” in *Communications of the ACM* (49(4), 2006), a special issue on “Evaluating Exploratory Search Systems” in *Information Processing and Management* (44(2), 2008). Exploratory search systems support users through information visualization and multimedia presentation and allow users to browse and explore an information collection to refine queries.^[20,21] The third trend is that retrieval systems and search engines start to provide more tools for users to manipulate retrieval results, so that they may make better use of retrieved items. It becomes evident that these trends have a common goal of providing more and better supports to users by increasing the functionality and flexibility of traditional IRS.

By moving beyond browsing, navigating, and retrieval, IRSS focus on a wide range of supporting functionalities, including summarization, exploration, analysis, knowledge discovery, results organization, retrieval strategy recommendation, and so on.^[5–7,22] The objective of an IRSS is to support many different types of user tasks in finding and utilizing information, in a similar way that a decision support system (DSS) assists managers in decision making.^[23]

Characteristics of IRSS

As the next generation retrieval systems, IRSS are extensions of IRS. In order to provide more supporting functionalities by IRSS, we need to design and implement new models, languages, utilities, and tools to assist a user in investigating, analyzing, understanding, and organizing a document collection and search results. These tools allow a user to explore both the semantic and structural

information of each individual document, as well as the entire collection. An IRSS is a user-oriented system in the sense that a user plays a more central role, and the system plays a supporting role. First, the system should be very flexible so that a user can perform a wide range of tasks. In some sense, an IRSS is a platform that allows a user to work on tasks in information and knowledge search. A user can make decisions at various stages. Second, instead of being a passive system waiting for user queries, the system may actively support a user by providing useful information without being explicitly asked. Third, an IRSS is adaptive to a user by collecting implicit and explicit feedback through user-system interaction. Thus, an IRSS must have learning capacity. From the performance point of view, an IRSS emphasizes accuracy and effectiveness more than efficiency and online processing. Fourth, the results from an IRSS must be more than a simple ranked list of information items. Moreover, a user should be allowed to visualize, reorganize, and compare various search results from different perspectives.

An IRSS needs to manage a large class of models of data, information, and knowledge. Three related types of models need to be considered. Documents in a document collection serve as the raw data of IRSS. The document models deal with representations and interpretations of documents and the document collection. The retrieval models deal with search. The presentation/recommendation models deal with the representation and interpretation of results from search. A single document model, retrieval model, or presentation model may not be suitable for different types of users. Therefore, IRSS must support multiple models, and provide tools for users to manage various models.

The document models allow multirepresentation of documents. Granular computing will play an important role in the construction of document models.^[6,24,25] One can use hierarchical granulation for a document, namely, a layered and multiresolution representation of documents. The same document is represented in less detail at a higher level than at a lower level. With multimodel capability, a user can create different logical views of a document and logical links between documents, as well as compare and investigate various views. The resulting in-depth knowledge can help the user locate and infer useful information. The recent development of XML enables us to describe both the structural and semantic information of a document. Such information makes the construction of multirepresentation document models an achievable goal.

The retrieval models provide languages and tools to assist a user in performing tasks such as searching and browsing. IRSS should provide multistrategy retrieval. A user can choose different retrieval models with respect to different document models. The retrieval process of IRSS is no longer just keyword matching. Instead, it must consider different types of inference methodologies. Thus, an IRSS provides different inference models to meet various

needs from different users. Both deductive inference and inductive inference are considered. Recently, several models were proposed for inference on Web scale, and can be considered as possible choices for IRSS. For example, associative inference and analogical inference can help find relevant results more effectively.^[26] Variable precision logic can be used to develop reasoning method based on incomplete information source and under time constraints.^[27] Based on Simon's theory on rational choice,^[28] combining reasoning and search on the Web scale is proposed.^[29] which may also be related to the study of IRSS.

The presentation/recommendation models allow a user to view and arrange search results, as well as various document models. The same results can be viewed in different ways by using distinct presentation/recommendation models. Moreover, a user can analyze and compare results from different retrieval models.

An IRSS also needs to build various models of users to provide better and personalized support. An IRSS may actively collect user information, user-system interaction information, and various other logs to build user profiles. With deep knowledge of users, an IRSS may provide more intelligent support. For example, user models may help an IRSS to select the best combination of document, retrieval, and presentation models. The full function of an IRSS is achieved by managing these models, as well as the associated languages, tools, and utilities.

THE CONCEPTUAL ARCHITECTURE OF IRSS

Many retrieval systems are starting to provide more supporting functionalities to users. They are typically implemented by simply adding components to existing IRS. There is still a lack of conceptual framework that allows us to have a more systematic study. And one cannot expect great progress without such a framework. For this reason, we consider here a conceptual architecture of IRSS.

Our interpretation of IRSS draws extensively from the related field of Decision Support Systems (DSS).^[23] While DSS focus on supporting and improving decision making, IRSS focus on supporting and improving retrieval. The philosophy, principles, and techniques from DSS are applicable to IRSS by substituting the tasks of "decision making" for the tasks of "information retrieval." This view of IRSS is particularly reasonable if one considers the fact that it is necessary to obtain useful information in order to make intelligent and rational decision.^[5]

Gorry and Morton^[30] define DSS as "interactive computer-based systems, which help decision makers utilize data and models to solve unstructured problems." Turban and Aronson^[23] compare different definitions of DSS and suggest that DSS are "computer-based information systems that combine models and data in an attempt to solve unstructured problems with extensive user involvement through a friendly user interface." From these definitions,

we want to stress two important features of DSS pertinent to our interpretation of IRSS. One feature is the combination of data and models. Data are raw and uninterpreted facts. In order to make sense of raw data, one needs to construct various models. Therefore, a DSS deals with both data and their interpretations. The other feature is the emphasis on the user involvement.^[5]

A simple conceptual architecture of IRSS is shown in Fig. 1, consisting of a user interface subsystem, an information-management subsystem, a knowledge-based management subsystem, and a retrieval subsystem. Their main functionalities are summarized below:

- User interface subsystem: provides a friendly interface for user–system interaction (containing different functionalities, and tools to support retrieving and postprocessing).
- Information management subsystem: collects and manages data, information, and knowledge of a collection of information items.
- Knowledge-based management subsystem: manages various models (e.g., document models, retrieval models, presentation/recommendation models, and user models) to support other subsystem.
- Retrieval subsystem: performs the retrieval and inference tasks, and analyzes retrieval results from multiple perspectives and provides the results to users through user interface.

The four subsystems work together to provide retrieval support to users. The main concern of this architecture is based on a combination of the traditional architecture of IRS and DSS.

IMPLEMENTATION OF IRSS

In this section, we look at the implementation of IRSS by mentioning results from related fields and giving the granular computing basis of IRSS.

Fields Related to IRSS

To build a relatively new discipline, we need to draw ideas, techniques, results, and lessons from many other

fields. A few related fields are summarized below, in addition to previously mentioned DSS.^[5]

Expert systems

A well-established practice in expert systems is the separation of knowledge and inference engines. While the inference engine is logic-based and problem-independent, the knowledge base is domain-specific. Expert system shells that implement an inference engine can be used to build many different domain-specific expert systems. Similarly, we can build a knowledge-based IRSS by separating knowledge-base and management subsystems. An IRSS shell can be built that provides a set of domain- and user-independent tools. Another feature of expert systems is the explanation functionality. An expert system not only provides a solution, but can also give reasons to justify the solution. It is reasonable to insist on the explanation functionality of an IRSS.

Machine learning and data mining

By applying algorithms of machine learning, data mining, and especially text mining to documents stored in an IRSS, one may discover patterns and extract knowledge useful to a user. Such functionalities are particularly useful to users who are interested in exploratory searching and browsing. For example, a user can track trends in a particular area or discover emerging topics from the constantly changing document collection. A user may also discover links between different documents or research areas.

Computer graphics and information visualization

In many cases, a user may not want the details about particular documents. A user may want to have a general feeling before going to a more in-depth analysis. This can be accomplished with a granulated view, in which details are omitted. Most current IRS present search results in the form of ranked list of individual documents. In an IRSS, a user should be able to use graphics and visualization tools to view a particular document model and retrieval results. Graphics and visualization techniques may enable users

Fig. 1 The conceptual architecture of IRSS.

easily to perform qualitative inference and analysis at multiple levels.

Intelligent information agents

Intelligent information agents have been used by many IRS to collect information and interact with users. The potential of agents needs to be further explored in IRSS. In particular, a user should be allowed to construct a personalized agent to interact with an IRSS. The autonomy and learning capabilities of agents make them attractive to both IRSS and users.

Granulation in IRSS

An important task of an IRSS is the management of various models. Typically, these models provide multiview and multilevel representations of the information items and users. In order to obtain such representations, the recently proposed theory of granular computing may provide the required theoretical and technological basis.^[31]

Document space, user space, term space, and retrieval-results space can be granulated respectively, to achieve multilevel and multiview representations. The four types of space granulation are related to each other. To provide retrieval results for different types of users, user space is granulated. A user granule may require a specific type of retrieval-result granule. Term space is granulated to support document-space and query-space granulations. An IRSS can recommend relevant terms to users for refining a query based on different levels of term granulation. Document space is granulated to different categories and the document granules can be retrieved based on relevant-term granules.

Document-space granulation

Traditional IRS focus more on documents, and the associated granulations are always document clusters based on the contents of documents.^[1,12] This single view may not fully explore information and knowledge about a document collection. In general, a document collection can be granulated in at least three views: content view, structure view, and usage view.^[32]

From the content view, document-space granulation may reveal the relationships among different documents or relationships between a specific document and a given topic. From the structure view, citations and links among different documents can be considered as implicit connections, which provide a different kind of granulation.^[33] From the usage view, documents that are accessed together can be put into the same document granule.^[32]

User-space granulation

Different types of users have different needs, and hence they should be classified into different user

granules. User-space granulation is mainly based on user profiles and user access logs. Based on Web-usage mining, we can find interesting rules for certain types of users.^[34] User-space granulation is necessary for personalized retrieval support. The granulated user space will be useful for locating relevant retrieval-results granules.

Term-space granulation

In IRSS, terms are granulated into a hierarchical structure based on relationships among them. For example, some terms may be very specific and belong to a more general term, and some terms may be synonyms, etc. Manual and automatic thesauri (such as co-occurrence analysis and grammatical analysis) are concrete methods for one-level term-space granulation.^[35,36] In general, one may consider hierarchical classification methods for multiple-level granulations. A granule network of domain knowledge can be built based on term-space granulation.^[7,32] Document granulation can be based on this granule network of terms, and a document can be associated with term granules. For example, gene and protein names are used for building domain-knowledge structures for biomedical literature classification.^[37] In the retrieval process, if query terms are too general, an IRSS could suggest users to refine the query terms using the granulated term space. On the other hand, if user terms are too specific, the system could suggest users with synonyms, co-occurring words, or more general terms. The term-space granulation also can be used for retrieval-results granulation. Retrieval results can be organized into a granule network based on term-space granulation.

Retrieval-result-space granulation

In order to have an in-depth understanding of the retrieval results, one may granulate them to form a multilevel view. One way to achieve this is through the use of user-space granulation and term-space granulation. For example, by using term-space granulation, retrieval results may be organized to reflect different levels of generality of terms, which may meet the user needs at different level of details. Depending on user-space granulation, one may choose the right level of term-space granulation for presenting retrieval results. Retrieved documents can also be presented based on document-space granulations.

CONCLUSION

With the advance of any technology, we need to find new applications that realize its benefits. The introduction of IRSS is to take advantage of recent achievements in information and Web technologies on one hand, and to maximize the potential values of the Web on the other. A search engine equipped with more supporting

functionalities will enable users to make full and wise use of the Web. The main feature of an IRSS is to expand the functions of current retrieval systems beyond search, navigation, and browsing. Such systems will play an important role in the next generation of the World Wide Web and the study of WI.

This entry briefly discusses the fundamental issues of IRSS. We demonstrate that IRSS represents the next generation in the evolution of retrieval systems, from DRS to IRS, and from IRS to IRSS. A conceptual architecture of IRSS is proposed. Regarding the implementation of IRSS, we examine a few related fields. Granular-computing theory is used to obtain multiview and multilevel representations through term-space, user-space, document-space, and retrieval-results-space granulations. These multiple representations may enable an IRSS to support users more intelligently.

Information Retrieval Systems

Ray R. Larson

School of Information, University of California—Berkeley, Berkeley, California, U.S.A.

Abstract

Information retrieval (IR) systems aim to select relevant material from large collections of information in response to user queries. The approaches used to accomplish this have been the focus of much research and development, and have led to the algorithms underlying many commercial and Web-based search engines today.

This entry describes the common components that go into the design of IR systems (from text processing to inverted file indexes). The major classes (or models) of retrieval algorithms (Boolean, vector, and probabilistic) are described along with formal definitions of the basic form of these algorithms and some of the variations in common use in IR research. In addition, the entry examines query expansion techniques, and in particular *relevance feedback*, and how they are used in IR systems.

INTRODUCTION

Information Retrieval (IR) is concerned with the storage, organization, and searching of collections of information. It has been part of significant part human technological development since the development of writing (or even earlier, since the mnemonic systems probably developed in prehistoric times can also be considered a form of mental IR). The earliest IR systems were the organization schemes of ancient archives and libraries, such as early Sumerian archives, or the “Pinakes” developed by Callimachus for the library of Alexandria. In the twentieth century the largest impetus to development of automated IR systems was the need to manage increasing larger quantities of information in business and scientific development. Early attempts at automating search capabilities for document collections involved techniques based on punched cards, as well as machines using optical sensing of codes on microfilmed documents.^[1] The concept of using machine-based systems for storage and retrieval of information was popularized by Vannevar Bush’s article “As We May Think” in 1945.^[2] The term “information retrieval” was coined by Mooers in 1950.^[3]

The goal of any IR system is to select the informational items (texts, images, videos, etc. which we will refer to as “documents”) that are expected to be relevant for a given searcher (or user) from a large collections of such items. Today these collections range from small sets of items on an individual’s personal computer to the vast resources of the World Wide Web. In all cases the task is the same: to extract some set of items that searchers *wants to have* from all of those they *do not want*.

This is not a simple task, and involves not only the technical aspects of constructing a system to perform such selection, but also aspects of psychology and user behavior to understand what differentiates the desired items

from the undesired from the particular user’s point of view. In this entry, we focus on the technical aspects of the system and leave the many issues of user interaction in search systems to the entry “User-Oriented and Cognitive Models of Information Retrieval.” We also do not consider, except in passing, the specific aspects of collections or of measuring relevance and search effectiveness. The entries “Information Retrieval and Evaluation,” “Test Collections,” “Web Information Retrieval,” and “TREC (Text Retrieval Evaluation Conference)” cover these aspects of IR in detail. We also note that that we will focus on computer-based IR systems and will not attempt to cover other types (indexes, catalogs, etc.), nor will we spend time discussing the related field of database management. Note also that this entry does not attempt to cover *all* of the myriad variations of approaches to IR that have been tested over the years, but only those we consider to be of interest and that have been shown to be effective in IR evaluations.

In this entry, and in much of the history of IR research, the focus has been on the system and how to obtain the best possible results using some collection of documents with predefined set of “correct” answers (known as a *test collection*). This is sometimes referred to as the laboratory model of IR, where the system and its algorithms are the primary foci of the research and user aspects of the system are considered hardly at all. There are many critiques of this laboratory approach, but it has the advantage of allowing comparability between IR systems in terms of standardized measures of effectiveness for a given collection and set of queries.

This entry describes the common components that go into the design of IR systems. The major classes (or models) of retrieval algorithms (Boolean, vector, and probabilistic) are then described along with formal definitions of the basic form of these algorithms and the

variations in common use in IR research. This section is an expansion and update of a similar description appearing in Larson.^[4] We then examine query expansion techniques, and in particular *relevance feedback*, and how they are used in IR systems. Finally, we conclude with a short discussion of experimental IR systems and their relation to commercial and public IR systems.

INFORMATION RETRIEVAL SYSTEM COMPONENTS

Information retrieval systems are made of a number of software components (varying in details from system to system) that are concerned with the primary functions of the system. These are: 1) accepting input in the form of documents, extracting information from those documents and storing that information in a form that can be quickly accessed for matching to user searches; and 2) accepting user queries and converting those to a form that can be compared to the stored information about documents. These two processes are often referred to as “indexing” and “retrieval.” In this section, we describe the common processes for indexing and retrieval, and indexes for matching the content of queries and documents. The retrieval models for ranking the results are discussed in the following section.

Text Processing

Fig. 1 shows an abstract representation of an IR system. All IR systems rely on two interdependent processes to

make their stored items (*records*, *documents*, or *document representatives*) accessible to users: *indexing* and *retrieval*. Although IR systems need not be computer-based (e.g., printed indexes and card catalogs can also be considered forms of IR systems), this entry focuses on computer-based systems.

The indexing process in IR systems (right-hand side of Fig. 1) is concerned with deriving a representation of a document according to the rules and processes set up for the particular system. One of simplest forms would be to extract all of the words occurring in each document and store them in an index along with an indication of which document they came from. This is commonly known as *binary indexing*, that is, a given word is either associated with a document, or it is not. Alternatively, an IR system may use some form of *weighted indexing*, where words are assigned to documents with an associated numerical weight indicating the importance or significance of that term to the document.^[5] Indexing will often also identify word position within a document, sometimes with enumeration of paragraph, sentence, and word position within a sentence. Such indexing can be used to determine proximity constraints for a query in a Boolean system (e.g., words in the query must occur in the same sentence or paragraph), or proximity weighting in ranked systems.

More commonly, the document normalization and index creation involve more complex text processing of the document contents than simple word extraction (the central trapezoid in Fig. 1). In the rest of this entry, we will use “terms” to indicated elements of a document

Fig. 1 Structure of an information retrieval system.

stored in the index. Terms may be words, or phrases, or some mapping of document content words to controlled vocabularies. The typical stages of text processing for document indexing may include

1. **Structural identification:** Recognition and selection of document elements based on document structure (e.g., selecting the title or author of the document). Because the structured document markup XML is now commonly used for the majority of documents available online, it has become relatively simple to identify and extract the significant structural elements of documents. Indexing may also store indications of the source of extracted terms in the index itself, permitting searches for both content and structure.
2. **Tokenization:** Individual “tokens” in the content are extracted. Tokens are portions of the content, typically sequences of alphabetic and numeric characters. Typically this involves ignoring spacing, page boundaries, and punctuation. The result is a set of tokens which may become terms in the index, or go through further processing. When individual words are extracted, their original positions in the content may also be retained in the indexes so that, for example, words near each other in the original text can be identified.
3. **Token pattern recognition:** Tokens may be examined to identify particularly meaningful or useful patterns. These may include such things as recognition of URLs or identifying sequences of capital letters (or capital letters with periods following them) as potential acronyms.
4. **Normalization of tokens:** This typically involves changing the capitalization of tokens to a single form (all lower case, for example). In some systems diacritics (accents, umlauts, etc.) may be removed and replaced with the appropriate base letter alone, or have multiple letters substituted. Some system may create duplicate tokens normalized in this fashion while retaining the original as well.
5. **Part of speech tagging:** Natural language processing (NLP) techniques such a part of speech tagging may be used to identify the different parts of speech in the content. Because the most common type of search is for nouns and noun phrases, this can be used to identify and extract noun phrases for special treatment.
6. **Stopword processing:** IR systems may have lists of words considered to be worthless in retrieval (these typically include articles like “an,” “the,” “a”). Some systems have different stopwords lists for each of identified structural elements, or for each index. Stoplists may also specify classes of tokens (such as numbers) or parts of speech.
7. **Stemming or morphological analysis:** Many IR systems use some form of stemming to collapse various inflected forms of a word (e.g., cat and cats) into a single form. Stemming uses simple rule-based

processing to perform this task and often does a poor job on some words. Morphological analysis typically uses a combination of exception dictionary lookup and rules. The intent of either is to have a single form of a word used in the indexes for all forms of that word.

Systems may include various combinations and variants of these processes. For example, some systems include both the “stemmed” form and original forms of terms, generating a table of original forms for each stem encountered during indexing and then using all forms during search. One advantage of this approach is that searches may be constrained to the original forms when needed, such as when the stemmed form is too inclusive.

As indicated in Fig. 1, both document indexing and query processing require similar or identical text processing steps. This is to ensure that the tokens from the users query are comparable with the tokens extracted during document indexing.

Indexes and Query Matching

The results of text processing on incoming documents are stored in the indexes of the IR system. These indexes provide a fast lookup mechanism for each token extracted by the text processing, along with other information including some identifier for the document(s) that the token came from, and usually other information, such as statistical information about the frequency of occurrence of the token in each document, and in the collection as a whole, and possibly information about the location that each token came from in each document.

The specific file structures used for the indexes vary from system to system, but the most common are some form of “inverted file,” where the data on all occurrences of a token in a collection are organized by a single instance of the token itself. This allows all of the data for resolving most queries to be fetched by a single lookup in the index for each token. The “comparison/matching” part of the processes shown in Fig. 1 is responsible for this task. This tends to be fairly common across a wide variety of IR systems, regardless of their type or “model.” The result of matching (or index lookup) is an unordered set of tokens and their associated information from the indexes, that were also in the *normalized query* (i.e., the results of applying the same text processing steps to the content of query that were applied to the stored documents).

INFORMATION RETRIEVAL MODELS AND RANKING

The true differentiation between IR systems occurs in the variations in the Text Processing and Ranking portions of Fig. 1. The different approaches to deriving a ranked

list of potentially relevant documents from the index matching results are often referred to as the “IR model.” In this section, we will examine the main IR models and how they obtain this ranking of potentially relevant documents.

There are three main classes of retrieval models: Boolean, vector, and probabilistic. In addition there are many systems that are hybrids of two or more of these models (e.g., a vector system with Boolean result limiting features). We begin with some formal definitions of system elements that are common to all of the models, and then examine each model in turn.

In an IR system, we have a collection, **D**, of N documents, indexed by a set, **T**, of M unique index terms or attributes. An individual document in the collection, D_i , may be represented as a vector of index term weights:

$$D_i = (w_{i1}, w_{i2}, w_{ij}, \dots, w_{iM})$$

The value of each w_{ij} term weight is determined by the indexing function applied. These values may represent binary indexing, (where $w_{ij} = 1$ if term T_j occurs in document D_i , and $w_{ij} = 0$ otherwise), simple term frequency weights (where each w_{ij} represents the number of times index term T_j occurs in document D_i), to more complex probabilistic weighting schemes (where w_{ij} is based on an estimation of the conditional probability that users would consider D_i to be relevant given that their query contains the term T_j).

The set of index terms, **T**, consists of any searchable attribute associated with the documents in the collection. These may be word stems, words, phrases, or other elements (such as class numbers) that occur in the text of the document or derived during text processing. They may also include associated elements that are not index terms in a conventional sense, such as related terms or cross-references from a thesaurus, citation information, or references to other documents (e.g., hypertext links). These index terms may be formally represented by an *inverted file*, where each index term, T_j has an associated vector of weights, I_j such that:

$$I_j = (w_{1j}, w_{2j}, w_{ij}, \dots, w_{Nj})$$

The document and index term vectors can be seen as a $N \times M$ matrix of w_{ij} weights. Thus, the collection of documents can be viewed as a matrix where the rows are individual document vectors and the columns the individual term vectors. In some systems the inverted file may also include positional information on the occurrence of the terms, and even include weights for the document, paragraph, and sentence level.

In virtually all IR systems, the inverted file is commonly used in retrieval operations instead of the document vectors.

Each query Q_k from the set of queries, **Q**, submitted to the system may be represented as a vector of index term weights:

$$Q_k = (y_{k1}, y_{k2}, y_{kj}, \dots, y_{kM})$$

where y_{kj} is the weight assigned by the user or system to term T_j in the k^{th} query.

The Boolean Model

The earliest retrieval model was the Boolean model based on Boolean logic. Systems using the Boolean model include most of the earliest commercial search services (like DIALOG or LEXUS/NEXUS), many online library catalogs, and many local search systems on individual Web sites. The Boolean model is a set-oriented model, where sets of documents are defined by the presence or absence of an individual index term. Using our formal definitions above, a single inverted file vector I_j can be considered as Boolean set, where each nonzero document weight in the vector defines a member of the set. In processing Boolean queries the sets representing the different search terms can be combined using the Boolean set operations intersection, union, and negation. These are usually expressed in a user's query as the *Boolean operators* AND, OR, and NOT.

AND: Set intersection generates a new output set from two input sets where the members (documents) shared by both sets become the members of the output set.

OR: Set union generates a new output set from two input sets where the members of either (or both) of the input sets are combined to become the new output set.

NOT: Set negation operates on a single input set, and generates a new set that contains all members (documents) that are not in the input set.

All of these operations can be performed using a simple binary inverted file, or more complex weighted inverted files. Note, however, that the unary NOT operation can be very expensive to process in inverted files, since the result set would be all documents in the system not included in the set. As a result most Boolean IR systems restrict the use of NOT to the binary “ANDNOT” operation which excludes any members of the right-hand set from the left-hand set.

In Boolean IR systems, the user is typically responsible for formulating a combination of terms and Boolean operators that will, it is hoped, select the relevant documents for the user's information need. Boolean systems are commonly extended by inclusion of other operators usually providing additional restrictions on set intersection

operations. For example, term proximity operations restrict a intersection to those documents that not only have both terms, but also have those terms within a specified distance from each other.

Pure Boolean IR systems have no inherent ordering of the result of Boolean query processing. Any order presented to the searcher is applied after the final Boolean result set is obtained. Many systems use some assumed useful ordering of the result set using document information (such as the date or author name of books in a library online catalog).

Many IR researchers have pointed out the major drawbacks with Boolean IR systems. These include

1. Boolean logic requires that the users be trained in construction of queries, because it is not intuitively obvious, and differs from common natural language usage. (e.g., a user seeking books on “cats and dogs” probably wants books on either, not just those that treat both.)
2. Boolean AND operations tend to be too restrictive. A search for “A AND B AND C” will eliminate any records that do not have all these terms. Those that have one or two of the three terms are rejected along with those that have none of the terms.
3. Boolean OR operations tend to be too inclusive. A search for “A OR B OR C” will retrieve any record with at least one of the terms, but no priority is given to those that include more than one of the terms.
4. Due to steps 2 and 3, the result of AND operations is often search failure, and the result of OR operations is often information overload.
5. Boolean logic treats each term equally, giving no priority to those that may be more important to the user’s need.
6. Boolean logic requires that the user’s query and the document indexing use the same terminology for matching to succeed.
7. Boolean logic does not permit the retrieved documents to be ranked in any significant fashion, documents are either retrieved or rejected with no “middle ground.”

Various extensions to Boolean systems have been proposed and tested over the years to allow result ranking based on applying weights to the terms and/or the Boolean operations. Examples include the use of “fuzzy sets,” where set membership is weighted instead of binary, and the “AND” operator returns the minimum of the two input weights, while the “OR” operator returns the maximum. The final result set is ordered by the weights.

Vector Model

The vector space model^[6] considers each document vector as described above to be a vector in an M -dimensional

space (i.e., one dimension for each term in the collection). Vector space IR systems base their ranking on how close together the document vectors and query vector are in this M -dimension space. This can be seen as calculation of a similarity measure based on the terms used in the query and in the documents in the collection. In practice, the inverted file is used to ensure that the processing considers only documents with at least one term in common with the query (otherwise in typical collections vast amounts of computation would be needed to process all document vectors even when they have no terms in common with the query).

In retrieval, partial match techniques based on the vector space model^[7] may be used to rank the documents in the collection in decreasing order of their similarity to the query. The simplest similarity function is the *inner product* of the document and query vectors:

$$\text{INNER}(D_i, Q_k) = \sum_{j=0}^M w_{ij}y_{kj}$$

A variety of other vector similarity measures normalize the value of the similarity to range between 0 and 1. Probably the most commonly used is the *cosine correlation*:

$$\text{COSINE}(D_i, Q_k) = \frac{\sum_{j=0}^M w_{ij}y_{kj}}{\sqrt{\sum_{j=0}^M w_{ij}^2 \cdot \sum_{j=0}^M y_{kj}^2}}$$

This is angular separation of the two vectors in the M -dimensional *vector space*.

The partial match techniques based on the vector model are distinguished by the different term weights and similarity measures used in calculating the *document weight* used to rank the retrieval. Some basic vector approaches are

1. Coordination-level matching. In coordination-level matching the term weights for documents (w_{ij}) and queries (y_{kj}) are binary and the inner product similarity function is used. The document weight calculated is simply the number of terms in common between the document and the query.
2. Cosine correlation with binary weights. This approach uses binary term weights and the cosine correlation to calculate the document weight.
3. Cosine correlation with frequency weights. This approach uses the term weights consisting of simple term frequencies, f_{ij} . That is, each w_{ij} is the number of times term T_j occurs in document D_i , and each y_{kj} is the number of times term T_j occurs in query Q_k . The

cosine correlation between these weighted vectors is calculated to yield the document weight.

4. Term frequency-inverse document frequency (TFIDF) weights. In TFIDF matching, term weights are calculated as follows:

$$w_{ij} = f_{ij} \cdot \log \frac{N}{n_j}$$

where n_j is the number of documents that contain term T_j . This gives the highest weights to terms that occur frequently in a given document, but relatively infrequently in the collection as a whole, and low weights to terms that occur infrequently in a given document, but are very common throughout the collection. Query terms are weighted by simple term frequency, as above, and the document weight is calculated as the inner product of the query and document vectors.

The TFIDF approach is the most common form of vector space weighting, although there are a very large number of variants for it. Most of the variants include some form of normalization of term frequency. Well-known IR systems that use the vector space model are Salton's SMART system,^[8] and more recently the open source Apache Lucene IR system originally developed by Doug Cutting.

Probabilistic Retrieval Methods

In the vector model there is an underlying assumption that documents which are similar to a query will be considered *relevant* to the information needs of the user who submits that query. Relevance is usually defined as a subjective assessment by a given user of the value or utility of a particular document in satisfying a particular need for information. We can say that for a particular search of an IR system, each of the documents in the collection either contains information that the individual wants, or it does not. If it does, then it is considered relevant, otherwise it is nonrelevant. The *document retrieval problem* is to select all of the records in the database that the user would find to be relevant, and reject all those that would be considered nonrelevant, that is, *all* and *only* the relevant documents should be retrieved.^[9]

Given the individual nature of relevance judgements, we can assume that there are no purely deterministic relationships between the terms used in indexing documents and the relevance of a given document, or between the terms used in searching for a document and the relevance of that document. Instead, these relationships are *probabilistic* in nature. This suggests that there are no perfect solutions to the document retrieval problem, but there may be approximate solutions. According to a significant body of theoretical work in IR, the appropriate approach

to IR is to rank each document in the database in descending order of its *probability of relevance* for a given user and query. This has been called the *probability ranking principle*.^[10]

There were originally two competing schools of thought on probability of relevance that have come to be known as Model 1^[5] and Model 2.^[11] These models were subsequently unified into a unified higher-level Model 3 and lower-level Model 0.^[12]

In discussing these probabilistic models we will assume that the set of all (present and future) documents in the collection, $\mathbf{D}$, and the set of all (present and future) queries, $\mathbf{Q}$, are described by binary vectors representing the presence or absence of index terms (although it should be noted that Robertson et al. (1982) make no such assumptions regarding representation). All possible document/query pairs (D_i, Q_j) , define a $\mathbf{D} \times \mathbf{Q}$ probabilistic event space. Within this event space we can define relevance as a relation which holds between certain document/query pairs:

$$R = (D_i, Q_j) | D_i \in \mathbf{D}, Q_j \in \mathbf{Q},$$

document D_i is judged to be relevant by a user submitting query; Q_j Nonrelevance, $\bar{R}$, is the complement of this relation.

We also define a subset of documents, $\mathbf{x} \subseteq \mathbf{D}$, such that all documents in $\mathbf{x}$ are represented by identical binary vectors i.e., those that are indexed by the same set of terms). Similarly, we have a subset, $\mathbf{y} \subseteq \mathbf{Q}$, of identical queries.

The notion of probability of relevance has a different interpretation under the four probabilistic models discussed in Robertson, Maron, and Cooper.^[12] In Model 1, first formulated in a somewhat different form by Maron and Kuhns,^[5] probability of relevance is seen as the relationship between a class of users (those submitting the same query) and a particular document:

$$P(R | \mathbf{y}, D_i)$$

Model 2, on the other hand, defines probability of relevance as a relationship between a class of documents and a particular user and use (or query):

$$P(R | Q_k, \mathbf{x})$$

The higher-level Model 3, proposed by Robertson, Maron, and Cooper,^[12] defines the probability of relevance as the relationship between an individual use (query) of the system and an individual document:

$$P(R | Q_k, D_i)$$

The lower-level Model 0, also proposed by Robertson, Maron, and Cooper^[12] and expanded by Wong and

Yao,^[13] defines the probability of relevance as a relationship between a class of queries and a class of documents:

$$P(R|y, \mathbf{x})$$

Most experimental and operational IR systems based on probabilistic principles have used forms of Model 2 for their implementation. For retrieval in a Model 2 system, the probability of relevance is used to define a Bayesian decision function, that is, for any particular query, documents with a given description $\mathbf{x}$ should be retrieved if

$$P(R|Q_k, \mathbf{x}) > P(\bar{R}|Q_k, \mathbf{x})$$

That is, documents should be retrieved if the probability of relevance is greater than the probability of nonrelevance.

This decision rule commonly takes the form of a discriminant function:

$$g_{Q_k}(\mathbf{x}) = \log \frac{P(R|Q_k, \mathbf{x})}{P(\bar{R}|Q_k, \mathbf{x})}$$

These probabilities are difficult to calculate directly, but Bayes theorem can be applied to convert them to the more convenient form:

$$g_{Q_k}(\mathbf{x}) = \log \frac{P(\mathbf{x}|R, Q_k)}{P(\mathbf{x}|\bar{R}, Q_k)} + \log \frac{P(R|Q_k)}{P(\bar{R}|Q_k)}$$

where $P(\mathbf{x}|R, Q_k)$ is the probability that if, for a given query, a particular query/document pair is judged relevant, then the document would have description $\mathbf{x}$. Since we are considering only a single query, we can define a subset, $\mathbf{D} \times Q_k$, of the $\mathbf{D} \times \mathbf{Q}$ event space, and the relevance relation:

$$R_{Q_k} = (D_i, Q_k) | D_i \text{ is relevant to } Q_k$$

where $R_{Q_k} \subseteq R$. If we define $P(R_{Q_k}) = P(R, Q_k)$, and $P(\bar{R}_{Q_k}) = P(\bar{R}, Q_k)$, and assume that index terms are stochastically independent with respect to the relevance or nonrelevance of a document then

$$P(\mathbf{x}|R_{Q_k}) = P(w_1|R_{Q_k})P(w_2|R_{Q_k}) \dots P(w_M|R_{Q_k})$$

$$P(\mathbf{x}|\bar{R}_{Q_k}) = P(w_1|\bar{R}_{Q_k})P(w_2|\bar{R}_{Q_k}) \dots P(w_M|\bar{R}_{Q_k})$$

where the w_i represent the individual index terms of the binary vector $\mathbf{x}$. We also define the symbols, $p_i = P(w_i = 1|R_{Q_k})$, and $q_i = P(w_i = 1|\bar{R}_{Q_k})$. Under these assumptions:

$$P(\mathbf{x}|R_{Q_k}) = \prod_{i=1}^M p_i^{x_i} (1 - p_i)^{1-x_i}$$

$$P(\mathbf{x}|\bar{R}_{Q_k}) = \prod_{i=1}^M q_i^{x_i} (1 - q_i)^{1-x_i}$$

By taking logs and substituting into the discriminant function, we get

$$g_{Q_k}(\mathbf{x}) = \sum_{i=1}^M w_i \log \frac{p_i(1 - q_i)}{q_i(1 - p_i)} + \sum_{i=1}^M w_i \log \frac{1 - p_i}{1 - q_i} + \log \frac{P(R|Q_k)}{P(\bar{R}|Q_k)} = \sum_{i=1}^M a_i w_i + K_1$$

where

$$a_i = \log \frac{p_i(1 - q_i)}{q_i(1 - p_i)}$$

and K_1 is a constant for any given query.

The Model 2 probabilities p_i and q_i can be calculated, or estimated, from frequency data. If there are N documents in the database and R' of them are relevant for a given query, and the i th term occurs in n_i of the documents of which r_i are relevant, then a_i can be calculated as

$$a_i = \log \frac{r_i(N - n_i - R' + r_i)}{(n_i - r_i)(R' - r_i)}$$

Notice that this assumes that relevance is known, or can be estimated, in order to provide the frequency data that are used to estimate the probabilities. In practice, what is usually done is to estimate the frequencies based on a sample of documents evaluated by the user, or when such information is not available this formula reduces to the inverse document frequency described above. Thus Model 2 is most effective applied in a secondary search, or *relevance feedback*^[14] situation, where documents retrieved in an initial search, often ranked according to a matching function based on rough estimates of the probabilities, are evaluated and the user's relevance judgments used to estimate Model 2 weights for a second search and re-ranking of the collection.

Okapi BM-25 algorithm

The most widely used form of a probabilistically based IR algorithm is known as the Okapi BM-25 algorithm developed by Robertson.^[15] The basic form of the Okapi BM-25 algorithm is

$$\sum_{j=1}^{|Q_c|} w_{(1)} \frac{(k_1 + 1)tf_j}{K + tf_j} \frac{(k_3 + 1)qtf_j}{k_3 + qtf_j}$$

where (in addition to the variables already defined)

$|Q|$ is the total number of terms in Q ,

$|Q_c|$ is the number of terms in Q that also occur in the document,

tf_j is the frequency of the j th term in a specific document,

qtf_j is the frequency of the j th term in Q ,

K is $k_1((1-b) + b \cdot dl/avdl)$,

k_1 , b and k_3 are parameters (set by experimentation for a given collection),

$avdl$ is the average document length,

$w^{(1)}$ is the Robertson–Sparck Jones weight:^[11]

$$w^{(1)} = \log \frac{\left(\frac{r+0.5}{R-r+0.5} \right)}{\left(\frac{n_j-r+0.5}{N-n_j-R-r+0.5} \right)}$$

n_j is the number of documents containing the j th term,
 r is the number of relevant components of a given type that contain a given term,

R is the total number of relevant components of a given type for the query.

The Robertson–Sparck Jones weights, when no relevance information is available, resolve to the inverse document frequency like the a_i measure above.

Logistic regression algorithm

Another approach to estimating probability of relevance uses the *Logistic Regression* (LR) algorithm originally developed by Cooper, Gey, and Dabney.^[16] The LR model of probabilistic IR attempts to estimate the probability of relevance for each document based on a set of statistics about a document collection and a set of queries in combination with a set of weighting coefficients for those statistics. The statistics to be used and the values of the coefficients are obtained from regression analysis of a sample of a collection (or similar test collection) for some set of queries where relevance and nonrelevance has been determined. More formally, given a particular query and a particular document in a collection $P(R|Q_k, D_j)$ is calculated (or estimated) and the documents or components are presented to the user ranked in order of decreasing values of that probability. To avoid invalid probability values, the usual calculation of $P(R|Q_k, D_j)$ uses the “log odds” of relevance given a set of S statistics, s_i , derived from the query and database, such that

$$\log O(R|Q_k, D_j) = b_0 + \sum_{i=1}^S b_i s_i$$

where b_0 is the intercept term and the b_i are the coefficients obtained from the regression analysis of the sample collection and relevance judgements. The log odds form can be used to rank results directly or be simply converted to probabilities:

$$P(R|Q_k, D_j) = \frac{e^{\log O(R|Q_k, D_j)}}{1 + e^{\log O(R|Q_k, D_j)}}$$

The form of the LR algorithm used in the Cheshire II IR system^[17,18] is

$$\begin{aligned} \log O(R|Q, C) = & b_0 + \left(b_1 \cdot \left(\frac{1}{|Q_d|} \sum_{j=1}^{|Q_d|} \log qtf_j \right) \right) \\ & + (b_2 \cdot \sqrt{|Q|}) + \left(b_3 \cdot \left(\frac{1}{|Q_d|} \sum_{j=1}^{|Q_d|} \log tf_j \right) \right) \\ & + (b_4 \cdot \sqrt{dl}) + \left(b_5 \cdot \left(\frac{1}{|Q_d|} \sum_{j=1}^{|Q_d|} \log \frac{N - n_j}{n_j} \right) \right) \\ & + (b_6 \cdot \log |Q_d|) \end{aligned}$$

where (in addition to the variables already defined above)

dl is the document length measured in bytes,

N is the number of documents in the collection,

b_i are the coefficients obtained through the regression analysis.

The LR approach to IR is one of a class of approaches that attempt to “learn” how to rank based on collected previous results. Other approaches use methods ranging from machine learning to genetic algorithms to learn the best ways of ranking results, usually for specific collections.

Language models

A rather different approach to probabilistic IR is based on language modeling originally developed for applications such as automatic speech recognition, machine translation, and OCR correction. A “language model” as used in IR systems is simply the statistical distribution of terms in documents and the collection as a whole. In language model-based IR instead of attempting to estimate probability of relevance, the system attempts to estimate the probability that a particular query was (or could have been) generated from language model for a given document. The results are then ranked according to this probability. The assumption is that if the query could have come from the document, then that document is likely to be relevant.

In the original description of language modeling, Ponte and Croft^[19] define the probability estimates used to rank a document in the search results as

$$P(Q_k|M_d)$$

where Q_k is a query (as above) and M_d is the language model for a given document. A simple approach to estimating this model would calculate

$$p_{ml}(T_j|M_d) = \frac{tf_j}{dl_d}$$

This is simply the *Maximum likelihood estimate* of the probability of term T_j in document d where tf_j is the raw term frequency in document d and dl_d is the length of document d (in tokens). The simplest ranking function is then the product of the individual term probabilities:

$$P(Q_k|M_d) = \prod_{T_j \in Q_k} p_{ml}(T_j|M_d)$$

The obvious problem with this ranking function is that it will be zero for any document that does not contain all of the query terms. Various approaches have been taken to normalize and *smooth* this basic model to avoid both the problem of going to zero and the implicit assumption that all documents with a given term share a common language model. Most implementations use much more sophisticated smoothing and model expressions than the simple unigram language model outlined here.

Language models have been quite effective in IR evaluation exercises like TREC (q.v.). The open source Lemur toolkit^[20] makes language modeling algorithms available to researchers and students.

Inference network models

Inference networks are a form of probabilistic model that uses networks of known probabilities of events (such as the a priori probability of a term occurring in a document) to infer the probability of unknown events (such as the probability of relevance for a given document and query). Inference networks were developed by Turtle and Croft,^[21] and are used in the INQUERY IR system. Inference networks can include nodes that are the results of Boolean operations into the probabilistic inference network.

Similar to inference networks are the IR application of neural networks where the probabilities of relevance given particular inputs are estimated by training the network, which involves adjusting the low-level probabilities of activation from one node to any connected nodes. The major difference is that in an inference net the inferential information is pre-encoded in the model (both as structure and parameters), while in neural nets nothing is encoded a priori, but instead a “blank” network is extensively trained on data and the inferences discovered based on this training.

Hybrid models

Many IR systems combine two or more of the basic models discussed above in a single system. The most common combination is to permit some form of Boolean operations or restrictions on a ranked result set. This may involve use of explicit Boolean or extended Boolean operations (such as proximity processing) to restrict a ranked result set to those items that satisfy the Boolean constraint. Other hybrid systems may use “data fusion” methods to combine results from different retrieval algorithms.^[22,23]

Combining probabilistic and (strict) Boolean elements, as well as operators to support various merging operations have been used in many systems as well. In implementation, strict Boolean operators and probabilistic searches (such as OKAPI BM-25 or LR) can be performed using the same inverted file structures, and they can be seen as two parallel *logical* search engines. Each logical search engine produces a set of retrieved documents. When a only one type of search strategy is used then the result is either a probabilistically ranked set or an unranked Boolean result set. However, both can be combined in a single query and the search results are evaluated using the assumption that the Boolean-retrieved set has an estimated $P(R|Q_{\text{bool}}, D) = 1.0$ for each document component in the set, and 0 for the rest of the collection. The final estimate for the probability of relevance used for ranking the results of a search combining strict Boolean and probabilistic strategies is simply

$$P(R|Q, D) = P(R|Q_{\text{bool}}, C)P(R|Q_{\text{prob}}, C)$$

where $P(R|Q_{\text{prob}}, C)$ is the probability of relevance estimate from the probabilistic part of the search, and $P(R|Q_{\text{bool}}, C)$ is the Boolean. In practice the combination of strict Boolean “AND” and the probabilistic approaches has the effect of restricting the results to those items that match the Boolean part, with ranking based on the probabilistic part. Boolean “NOT” provides a similar restriction of the probabilistic set by removing those document components that match the Boolean specification. When Boolean “OR” is used the probabilistic and Boolean results are merged (however, items that only occur in the Boolean result, and not both, are usually reweighted to the lower range of probabilistic results).

QUERY EXPANSION AND RELEVANCE FEEDBACK

In many IR tasks the queries submitted by a searcher are often very short and sometimes ambiguous. The goal of query expansion is to create a larger query from the searcher’s initial expression and to use that to obtain (it is hoped) more relevant results. Some forms of query expansion take place in the initial text processing of the query (as discussed above) but the most effective methods involve obtaining relevance judgements on a sample of documents obtained using the initial query expression, and performing *relevance feedback* processing on those documents (shown as the dashed lines in Fig. 1).

Relevance feedback has been shown to be remarkably effective in improving the result of a query. The Vector Space and Probabilistic models take somewhat different approaches to relevance feedback. However, the main idea is to modify the existing query based on the judged

relevant and nonrelevant documents, usually extracting terms from the relevant documents and adding them to the query and also adjusting the weights for terms already in the query.

The most widely used Vector Space algorithm for relevance feedback is the Rocchio Method.^[24] The Rocchio method is defined by

$$Q_{\text{new}} = \alpha Q_{\text{old}} + \frac{\beta}{n_1} \sum_{i=1}^{n_1} R_i - \frac{\gamma}{n_2} \sum_{i=1}^{n_2} S_i$$

where

Q_{old} is vector for the initial query,

R_i is the vector for the judged relevant document i ,

S_i is the vector for judged nonrelevant document i ,

n_1 is the number of relevant documents chosen,

n_2 is the number of nonrelevant documents chosen,

α , β , and γ are parameters to tune the importance of the initial query and the relevant and nonrelevant terms.

Common settings are $\beta = 0.75$ and $\gamma = 0.25$.

The probabilistic models commonly use some form of the Robertson–Sparck Jones weights for relevance feedback. This appears in the Okapi BM-25 Formula above. In relevance feedback the portions of that formula that need relevance information are filled in from the judged relevant and nonrelevant documents, and new weights are calculated for the query terms based on resulting weights. In the Cheshire II system the Robertson–Sparck Jones weights are calculated and used to select a number of most highly weighted terms from the judged relevant documents to add to the initial query and to reweight the initial query terms. This expanded query is then searched using the same LR algorithm as the initial query.

One interesting, and effective, technique that has been used in many retrieval evaluations with good results is the so-called Blind or Pseudo relevance feedback. In this approach there is no searcher involved nor actual relevance judgements made. Because many (if not most) IR systems tend to have relevant documents at the top of their rankings, this approach assumes that some arbitrary number of the top-ranked documents from the initial search are in fact relevant and applies relevance feedback processing to them (usually with a corresponding number of assumed nonrelevant documents from the bottom of the initial ranking). Even though there is no user judgement involved in this process, it has on average improved the results for systems using this method. Generally, however relevance feedback is most effective when the searcher is directing the relevance choices.

CONCLUSION

Information retrieval systems aim to select relevant material from large collections of information in response to

user queries. The approaches used to accomplish this have been the focus of much research and development, and have led to the algorithms underlying many commercial and Web-based search engines today. The article on Web Search Engines goes into more detail on the approaches taken by the various Web search companies. Even though the specific algorithms of any particular search engine are considered proprietary “trade secrets,” we can safely say that all existing Web search engines use some combination of the models outlined above, usually with the addition of Web-specific ranking algorithms (such as Google’s PageRank that ranks Web pages based on the numbers of ingoing HTML links for that page, as well as other “reputation-based” metrics). Effective search is considered to be one of the critical requirements of the Web, and is also an essential requirement in corporate and academic databases, digital libraries, and library catalogs. Information retrieval systems, as described here, provide proven effective search capabilities to these important services of the digital age.

Abstract

Information scattering is an often observed phenomenon related to information collections where there are a few sources that have many items of relevant information about a topic, while most sources have only a few. This entry discusses the original discovery of the phenomenon, the types of information scattering observed across many different information collections, methods that have been used to analyze the phenomenon, explanations for why and how information scattering occurs, and how these results have informed the design of systems and search strategies. The entry concludes with future challenges related to building computational models to more precisely describe the process of information scatter, and algorithms which help users to gather highly scattered information.

INTRODUCTION

Whether one searches for research papers about a subject in journals, or for facts about a topic on the Web, a common observation is that there are very few sources (e.g., journals or Web pages) that contain many items of relevant information, while most sources have only a few. This phenomenon is referred to as *information scattering*, and has been a topic of research for over seven decades.

Although the first report on the phenomenon of information (or literature) scattering is generally attributed to Bradford,^[1] it became increasingly clear by 1900 that a large part of the scientific literature on any subject seemed to be scattered across an indefinite number of generalist and specialist journals, with no direct relationship to the subject.^[2] This phenomenon posed a problem for the bibliographic control of information because of the possibility of “missed literature” in any comprehensive search.

Bradford, a chemist turned librarian, helped to quantify this observation.^[1] He recorded a regularity in the numbers of papers on two scientific subjects across different journals. He noticed that if the journals in each of the two scientific subjects were first ranked in order of the numbers of papers they contain on a subject, and then divided into, say, three groups with an equal number of papers, the numbers of journals in successive groups grew in the ratio of 1: k : k^2 . For example, if 3000 papers on a subject were found in 800 journals, then the ratio of (ranked) journals, in successive groups of 1000 papers, is 42: 158: 600, or approximately 1: 3.8: 3.8^2 .^[3] The number of preselected groups can be other than three, which will result in a different number of journals in each group, but will result

in a similar regularity. This mathematical regularity, which predicts a core, middle, and peripheral groups of journals for any subject, is often referred to as *Bradford's Law of Scattering* and the resulting distribution of papers across journals as a *Bradford Distribution*.

When Bradford published the above quantitative findings, they were surprising as it suggested that the “missed literature” could be as much as two-thirds of the total for any subject. However, these results are relevant even today because current electronic databases (e.g., Web of Science or Scopus) analyze only a fraction of the world's journals leading to a similar result.

Subsequent to the publication of Bradford's^[1] paper, there has been considerable debate about inconsistencies in the verbal and graphical description of the law,^[4] and how to represent the law of scattering using more standard statistical measures such as frequency distributions. The latter has led to comparisons^[5] with other similar laws such as Zipf's Law^[6] and Lotka's Law^[7] which describe skewed distributions for other kinds of information phenomena (e.g., the distribution of words across books or authors across papers). Such hyperbolic distributions are referred to as the informetric laws and are studied in the broader field of Informetrics, generally defined to include all quantifiable aspects of Information Science.^[3,8] Bibliometrics, including bibliometric laws are (earlier) terms still used in the literature of information scattering.

Furthermore, there have been debates on how to define the concept of “subject”^[9] or “topic”^[10] (e.g., melanoma vs. melanoma treatment), which could produce different results when deriving Bradford distributions of papers across journals or studying the distributions of authors

across papers (Lotka's Law). However, despite these debates about specific details on the original formulation of Bradford's law of scattering, there is now general agreement that information scattering is a fundamental information phenomenon, and continues to be an active research area for bibliometricians, informetricians, scientometricians, webometricians, and other researchers.

This entry provides an overview of the research on information scattering based on five sections: (1) Types of information scatter; (2) Methods to analyze information scatter; (3) Explanations for the process of information scatter; (4) Implications of information scatter for search strategies and the design of search systems; and (5) Future research challenges.

TYPES OF INFORMATION SCATTER

One way to classify the different types of information scatter is based on how different granularities of *information objects* (e.g., articles, words, facts) are distributed across different granularities of *containers* (e.g., journals, books, Web pages). Several studies on information scatter have analyzed different combinations of information objects and containers, at different granularities. As discussed in the introduction, Bradford^[1] analyzed the distribution of articles across journals and Zipf^[6] analyzed the distribution of words within a book. More recently, research has analyzed the distribution of articles across online databases,^[11–13] the distribution of images across databases,^[14] and the distribution of facts about a topic across Web pages and Web sites.^[15,16] In each case, while the exact fitted curves (e.g., power law, exponential, Poisson) of the distributions vary, the researchers have found strong similarity to the overall regularity originally observed by Bradford. For example, as shown in Fig. 1, the distribution of facts across Web pages is best fitted by a discrete exponential curve.^[15]

Fig. 1 Distribution of facts about melanoma risk and prevention across high-quality healthcare pages. The distribution is best fit by a discrete exponential curve.

Source: From Bhavnani.^[15]

Nicolaisen and Hjørland^[9] have also classified the different types of information scatter in terms of (1) lexical scattering (words across collection of texts); (2) semantic scattering (concepts across texts); and (3) subject scattering (items useful to a given task or problem). Furthermore, the different types of information scatter constrain the relationships between object and container. For example, facts and articles about a topic can be in multiple Web pages or databases respectively. However, a particular article can be in only one journal. These constraints result in different relationships between information objects and containers.

METHODS USED TO ANALYZE INFORMATION SCATTER

There have been three principal methods used to quantitatively characterize information scatter: (1) Frequency distributions; (2) Coverage analyses; and (3) Network visualizations and analysis.

Frequency Distributions

Frequency distribution is a standard statistical method designed to show for a dataset the relationship between a ranked list of categories of observations (e.g., 1–10 journals, 11–20 journals, etc.) and the number or frequency of data items that fit into each category (e.g., 200 articles occurring in 1–10 journals). Typically the categories are placed on the *x*-axis and the number or frequency is on the *y*-axis, however, several researchers such as Zipf^[6] chose to transpose them. Fig. 1 shows the frequency distribution of the number of facts about a topic across a ranked list of pages.^[15] Depending on the data and the point that the researcher wishes to make, frequency distributions have been used in formats other than the above to characterize information scatter. For example, while the graph in Fig. 1 represents unique occurrences of facts in each category, a *cumulative frequency* distribution includes successive values. Furthermore, when there are a large number of categories and frequencies, the distribution are often plotted on a log–log plot which significantly reduces the length of the *x*-axis for such large datasets, while preserving the overall relationship.

Coverage Analyses

While the above distributions describe the data, they cannot reveal the minimum number of information containers to visit to get all the information objects. To reveal such details, researchers use distributions which are focused on coverage. Fig. 2 shows how many databases are needed to find all the papers related to a subject.^[13] Such a distribution provides another measure for comparing the information scatter among topics or databases. Similar to Fig. 2,

Fig. 2 Distribution of the percentage of journal articles retrieved as a function of the number of databases accessed.
Source: From Hood and Wilson.^[13]

most results in information scatter studies have revealed that it takes many containers to get full coverage of information objects.

Network Visualizations and Analyses

Graphical networks are increasingly being used in a wide range of domains to analyze complex relationships such as information scatter. A network is a graph consisting of nodes and edges; nodes represent one or more types of entities (e.g., facts or Web pages), and edges between the nodes represent a specific relationship (e.g., a Web page contains a fact). Figure 3 shows a bipartite network (where edges exist only between two different types of entities) of how facts about melanoma risk and prevention, are contained in Web pages from the top 10 healthcare Web sites for melanoma information.

Networks have two advantages for analyzing information scatter: (1) They represent a particular relationship between different nodes and therefore can reveal patterns, such as how specific facts occur in different groups of Web pages and (2) They can be rapidly visualized and analyzed using a toolbox of network analysis methods and visualization algorithms. For example, Fig. 3 shows a force-directed layout algorithm which helps to visualize the relationship between Web pages and facts.^[17] The algorithm simulates placing attractive forces between connected nodes and a weakly repulsive force between all nodes. The result is that facts which co-occur in many of the same pages are placed close to each other and close to the pages that mention them. The analysis revealed that there are two subgroups of pages (the top and bottom), which contain a concentration of different sets of facts, while another group of pages in the middle that contain both groups of facts. Furthermore, the visualization

reveals common and rare facts, and how they co-occur across the pages. Such visualizations (and related quantitative network measures used to verify the visual observations) therefore help to reveal new regularities about information scatter which are often concealed in aggregate measures such as frequency distributions.

EXPLANATIONS FOR INFORMATION SCATTER

While there are many studies that quantify information scatter, there are relatively few explanations for why information occurs. This scatter of articles across journals has been explained as follows: Although each field has a core set of a few journals where authors publish, there are many other journals with suitable subject scopes. Furthermore, because papers are often interdisciplinary in nature and therefore relevant to more than one field, authors may publish such papers in journals that are close to as well as distant to their main field. This results in the core journals of one field becoming the peripheral journals of another field.^[18] Hood and Wilson^[13] posit that information scatter could be related to the interdisciplinarity of topics: the more interdisciplinary a topic, the higher probability that the authors would choose to publish results in either a generalist journal related to the interdisciplinary topic or in a specialist journal of a field other than the authors' academic field. This publishing practice may result in the high scatter of such topics across journals and databases.

Bhavani^[15] found that facts (e.g., high UV exposure increases your risk of getting melanoma) about five healthcare topics (e.g., melanoma risk and prevention) were scattered across high-quality Web sites specializing in that topic. There were many pages which had few facts, few pages that had many facts, and no pages that had all

Fig. 3 The scatter network for melanoma risk/prevention showing how 14 facts (white labeled nodes) occur in 108 relevant pages (solid nodes). The white arrow points to a common fact and the black arrow points to a rare fact.

Source: From Adamic et al.^[17]

the facts. Furthermore, the analysis revealed that underlying this distribution were three different page profiles that varied in fact density and role: *General pages* which contain many facts in medium amount of detail and play the role of providing an overview of the topic (e.g., What Are the Risk Factors for Melanoma?); *Specific pages* which contain few facts in a large amount of detail and play the role of providing detailed description of a few facts (e.g., Sunscreens and Prevention of Malignant Melanoma); and *Sparse pages* which contain few facts in a small amount of detail and were pages that were of broader topics (e.g., Skin Cancer) with a brief reference to the search topic.

The above observations led to the *information saturation model*^[19] to explain this phenomenon. In this hypothetical model, Web page authors follow a process of *accumulation* to progressively add facts in detail to a page, until a length and detail saturation threshold is reached. At such a threshold, because the Web page becomes unwieldy and difficult to read, Web page authors heed design guidelines by removing detail about facts from these pages through the process of *abstraction* resulting in general pages. Concurrently, they also might be creating new pages to elaborate particular facts in high detail through the process of *specialization* resulting in specific pages. Finally as a topic becomes more important, the topic *permeates* otherwise irrelevant pages resulting in sparse pages. The above processes could lead to the creation of a large number of specific pages and sparse pages, while constraining the total

number of general pages. However, while there have been quantitative models that generate different informetric phenomena such as the distribution of papers per author,^[20] there appears to be no research that has quantitatively modeled phenomena related to information scatter.

IMPLICATIONS OF INFORMATION SCATTER FOR SEARCH AND DESIGN

While there have been claims that Bradford's law has been useful for selecting journals for libraries or databases, there are actually no references about how it has been applied in practical library and information sciences.^[9] Some researchers have explored the implications for the phenomenon of information scatter to search strategies, and the design of systems to help users find comprehensive information. Bates^[21] proposed that because the core, middle, and peripheral regions of the Bradford distribution have different densities of relevant articles, they imply the use of different search strategies. For example, when searching for articles, users should identify the core set of journals for that topic. Because there is a high density of relevant articles in the core, browsing could be sufficient to find many relevant articles. In contrast, because the middle region has a lower density of relevant articles, users need to use queries that exploit systematic organizations of articles such as indexes. Finally, in the peripheral

region where articles are very scattered, users need to use strategies such as *citation tracking* to quickly find the relevant articles.

While the above search strategies are implied by the density of articles *across* the different regions of the Bradford distribution, Bhavnani^[15] leveraged the idea of information density *within* Web pages through the *general-specific-sparse* search strategy. This strategy recommends that users first find and read general pages about a topic to get an overview of the topic and to ensure that they do not miss any facts. Next (as often prescribed by earlier authors such as Kirk),^[22] users should find specific pages that specialize in the facts they found within the general pages, to help elaborate facts of interest. Finally, they should broaden the search by finding and reading sparse pages to understand how the topic of interest relates to other topics.

The above strategy was operationalized in a Web site called the *Strategy Hub*^[23] to help users find comprehensive healthcare information. In this system Web pages were organized in terms of general, specific, and sparse pages, and users were guided to read pages that followed that strategy. In a controlled experiment, users of the Strategy Hub found more comprehensive information in the same amount of time compared to equivalent users of MedlinePlus and Google.

FUTURE RESEARCH CHALLENGES

Future research challenges include: (1) building models to understand the process of information scatter; and (2) algorithms to help users gather highly scattered information. As described earlier, although a few researchers have proposed explanations for information scatter, none of these have been formalized into a model and tested to simulate the process of information scatter. Future research should therefore develop computational models to simulate information scatter over time so that the phenomenon can be precisely understood. The second area of potential future research is to leverage a precise understanding of information scatter to develop new algorithms which either automatically aggregate different types of scattered information or work interactively with users to help them find comprehensive information.

Abstract

The purpose of this entry is to provide an overview of information science as a field or discipline, including a historical perspective to illustrate the events and forces that shaped it. Information science is a field of professional practice and scientific inquiry dealing with effective communication of information and information objects, particularly knowledge records, among humans in the context of social, organizational, and individual need for and use of information. Information science emerged in the aftermath of the Second World War, as did a number of other fields, addressing the problem of information explosion and using technology as a solution. Presently, information science deals with the same problems in the Web and digital environments. This entry covers problems addressed by information science, the intellectual structure of the field, and the description of main areas—information retrieval, human information behavior, metric studies, and digital libraries. This entry also includes an account of education related to information science and conclusions about major characteristics.

INTRODUCTION

The purpose of this entry is to provide an overview of information science as a field or discipline, including a historical perspective to illustrate the events and forces that shaped it.

Information science is the science and practice dealing with the effective collection, storage, retrieval, and use of information. It is concerned with recordable information and knowledge, and the technologies and related services that facilitate their management and use. More specifically, information science is a field of professional practice and scientific inquiry addressing the effective communication of information and information objects, particularly knowledge records, among humans in the context of social, organizational, and individual need for and use of information.^[1] The domain of information science is the transmission of the universe of human knowledge in recorded form, centering on manipulation (representation, organization, and retrieval) of information, rather than knowing information.^[2]

There are two key orientations: toward the human and social need for and use of information pertaining to knowledge records, on the one hand, and toward specific information techniques, systems, and technologies (covered under the name of *information retrieval*) to satisfy that need and provide for effective organization and retrieval of information, on the other hand. From the outset, information science had these two orientations: one that deals with information need, or more broadly human information behavior, and the other that deals with information retrieval techniques and systems.

Information science is a field that emerged in the aftermath of the Second World War, along with a number of new fields, with computer science being but one example. While developments and activities associated with information science already started by the end of 1940s, the very term “information science” came into full use only at the start of the 1960s. A significant impetus for the coalescence of the field was the *International Conference on Scientific Information*, held in Washington, D.C., November 16–21, 1958, sponsored by the (U.S.) National Science Foundation, the National Academy of Sciences—National Research Council, and the American Documentation Institute, and attended by some 1000 delegates from 25 countries. The conference was meticulously planned for over 3 years and attracted wide international attention. The 75 papers and lively discussions that followed, all recorded in the *Proceedings* of over 1600 pages, affected the direction of research, development, and professional practice in the field for at least a decade if not longer.^[3] It also affected the internationalization of the field and the approaches used. They became global.

This entry covers problems addressed by information science, the intellectual structure of the field, and the further description of main areas—information retrieval, human information behavior studies, metric studies, and digital libraries. At the end, the entry includes an account of education related to information science and conclusions about major trends.

PROBLEMS ADDRESSED

To understand information science, as with any other field, a description of problems addressed and methods used in

their solution is crucial. Generally, information science addressed the problem of information explosion and used information technology as a solution.

The rapid pace of scientific and technical advances that were accumulating since the start of the twentieth century produced by mid-century a scientific and technical revolution. A most visible manifestation of this revolution was the phenomenon of “information explosion,” referring to the unabated, exponential growth of scientific and technical publications and information records of all kinds. The term “information explosion” is a metaphor (as is “population explosion”) because nothing really exploded but just grew at a high rate, even exponentially at times. Simply put, information explosion is information and information objects piling up at a high rate. The problem this presents is getting to the right information as needed at a given time.

A number of scientists documented this growth, but none better and more vividly than Derek de Solla Price (1922–1983, British and American physicist, historian of science and information scientist), recognized as the father of scientometrics. In his seminal works, *Science since Babylon* followed by *Little Science, Big Science*, Price documented the exponential and logistical growth of scientific publications linking them with the growth of the number of scientists. The logistical growth started slow right after the appearance of the first scientific journals in the seventeenth century, accelerated by the start of the twentieth century and became explosive after the Second World War.^[4,5]

The impetus for the development of information science, and even for its very origin and agenda, can be traced to a 1945 article, “As We May Think” by Vannevar Bush (1890–1974), a respected MIT scientist and, even more importantly, the head of the U.S. scientific effort during World War II.^[6] In this influential article, Bush did two things: (1) he succinctly defined the critical and strategic problem of information explosion in science and technology that was on the minds of many, and (2) proposed a solution that was a “technological fix,” and thus in tune with the spirit of the time. Both had wide appeal. Bush was neither the first nor the only one that addressed these issues, but he was listened to because of his stature. He defined the problem in almost poetic terms as “The summation of human experience is being expanded at a prodigious rate, and the means we use for threading through the consequent maze to the momentarily important item is the same as was used in the days of square-rigged ships.” In other words, Bush addressed the problem of information explosion and the associated methods for finding relevant information.

As a solution, Bush proposed a machine, dubbed Memex, incorporating (in his words) a capability for “association of ideas,” and the duplication of “mental processes artificially.” A prescient anticipation of information science and artificial intelligence is evident. Memex,

needless to say, was never built, but to this day is considered an ideal, a wish list, an agenda, and, some think, a utopia. Information science is still challenged by the ever-worsening problem of information explosion, now universal and in a variety of digital formats, and the field is still trying to fix things technologically.

A number of scientists and professionals in many fields around the globe listened and took up Bush’s challenge. Most importantly, governments listened, as well, and provided funding. The reasoning went something like this: Because science and technology are strategically important for society, efforts that help them, information activities in particular, are also important and need support. In the United States, the United Kingdom, and other countries, this led to the support of research and development related to information problems and solutions. By the end of the 1940s information science was well on its way.

Bush also participated in the establishment of the National Science Foundation (NSF) in the United States. The National Science Foundation Act of 1950 (P.L. 81-507) provided a number of mandates, among them “to foster the interchange of scientific information among scientists in the U.S. and foreign countries” [Section 3(a)3] and “to further the full dissemination of [scientific and technical] information of scientific value consistent with the national interest” [Section 11(g)]. The 1958 National Defense Education Act (P.L. 85-864) (the “Sputnik act”) enlarged the mandate: “The National Science Foundation shall [among others], undertake programs to develop new or improved methods, including mechanized systems, for making scientific information available” (Title IX, Section 901). By those mandates, an NSF division, which after a number of name and direction changes is now called the Division of Information and Intelligent Systems (IIS), has supported research in these areas since the 1950s. Information science evolution, at least in the United States, was greatly affected by the support of the U.S. government. In this respect it was not an exception. For instance, artificial intelligence, among others, was for decades supported by the U.S. government starting in the 1950s and ending by the 1990s.

Historically, one force affecting government support of information science, as of many other fields in the United States and a number of European countries, had to do with the cold war. Among others, one impetus was the establishment in 1952 of the All-Union Scientific and Technical Information Institute of the Academy of Sciences of the USSR (Russian acronym: VINITI). VINITI implemented a massive gathering and bibliographic control of scientific and technical information from around the world, eventually covering some 130 countries in 66 languages; it employed thousands of scientists and engineers full- and part-time. In the framework of the Cold War, VINITI was repeatedly brought up as a challenge needing a response.

At the start, information science was directed solely toward information explosion in science and technology.

However soon it expanded to other areas, including business, humanities, law, and eventually any area of human endeavor. In all areas, the phenomenon of information explosion is continuing and even accelerating to this day, particularly in the digital and Web environments. Addressing the problems of dealing with information explosion in any human area where information and knowledge records are overbearing is at the heart of information science. The approach to these problems involves a number of disciplines; in other words, information science, as many other modern fields, is interdisciplinary in nature.

In its goals and activities, information science established early, and maintains prominently, a social and human function—not only a technological one. On the social level, it participates actively, with many other fields, in the evolution of information society around the globe. Yet information science also has an individual human function. It relates to searching for and use of information as done by (or on behalf of) individuals. People individually search for and use relevant information. For information science, managing information is a global, social function, while providing and using information is an intense individual function.

INTELLECTUAL STRUCTURE

Information science, like any other field, has a dynamic intellectual structure; the objects of study and practice appear, change, disappear or are emphasized, realized, and interwoven in different ways over time. A general framework for the intellectual structure for the field can be derived from the Three Big Questions for information science as identified by Bates:^[2]

1. The physical question: What are the features and laws of the recorded information universe?
2. The social question: How do people relate to, seek, and use information?
3. The design question: How can access to recorded information be made most rapid and effective?

Indeed, when looking at the literature of information science since its emergence to this day, the general structure can be discerned from these questions in both research and practice reported. While they can be approached individually, the three questions are not independent but interdependent. Effective design is highly dependent on the consideration of social and physical features. Over time, details in the answers differed greatly. But, as is seen from three examples below, the general structure stands.

Three examples illustrating the intellectual structure of information science spanning some five decades are presented here. The first one is the enumeration of topics in the proceedings of the mentioned 1959 *International*

Conference on Scientific Information.^[3] The second one is an author cocitation analysis mapping information science for the years 1972–1995.^[7] And the third one is a similar analysis, using the same methods, mapping information science for the years 1996–2005.^[8] Author cocitation analysis is a statistical and visualization method developed in information science that allows for mapping of connections between authors in a given domain and identifying clusters or oeuvres of work in that domain. The raw data reflects the number of times selected author pairs are cited together in papers, regardless of which of their work is cited.

The 1959 Proceedings had seven areas covering the research, practice, and interests of information science at the time and illustrating the intellectual structure of the field by the end of 1950s. These were

1. *Literature and reference needs of scientists*. An example of a title of a paper in the area: An Operations Research Study of the Dissemination of Scientific Information.
2. *The function and effectiveness of abstracting and indexing services*. A paper example: All-Union Institute for Scientific and Technical Information (VINITI).
3. *Effectiveness of monographs, compendia, and specialized centers. Present trends and new and proposed techniques and types of services*. A paper example: Scientific, Technical, and Economic Information in a Research Organization.
4. *Organization of information for storage and search. Comparative characteristics of existing systems*. A paper example: The Evaluation of Systems Used in Information Retrieval.
5. *Organization of information for storage and retrospective search. Intellectual problems and equipment considerations in the design of new systems*. A paper example: Linguistic Transformations for Information Retrieval.
6. *Organization of information for storage and retrospective search. Possibility for a general theory*. A paper example: The Structure of Information Retrieval Systems.
7. *Responsibilities of government, professional societies, universities, and industry for improved information services and research*. A paper example: Differences in International Arrangements for Financial Support of Information Services.

Results from the next two studies are comparable—they used the same set of basic data (major journals in information science) and the same method (author cocitation analysis and mapping).^[7,8] The authors of both studies mapped clusters of authors, classifying their areas of publications in a number of categories—they labeled the categories—and showing the relation or lack thereof between

Table 1 Intellectual structure of information science as presented in studies of two time periods (labels provided by authors of respective studies).

1972–1995	1996–2006
1. Experimental retrieval (design and evaluation of IR systems)	1. User studies (information seeking/searching behavior, user-centered approach to IR, users and use)
2. Citation analysis (interconnectedness of scientific and scholarly literatures)	2. Citation analysis (scientometrics; evaluative bibliometrics)
3. Practical retrieval (applications in “real world”)	3. Experimental retrieval (algorithms, models, systems, evaluation of IR)
4. Bibliometrics (statistical distributions of texts and mathematical modeling)	4. Webometrics
5. General library systems (library automation, library operations research, services)	5. Visualization of knowledge domains (author cocitation analysis)
6. Science communication (including social sciences)	6. Science communication
7. User theory (information needs and users)	7. Users’ judgment of relevance (situational relevance)
8. Online Public Access Catalogs (OPACs) (design, subject searching)	8. Information seeking and context
9. Imported ideas (information theory, cognitive science, etc.)	9. Children’s information searching behavior (usability, interface design)
10. Indexing theory	10. Metadata and digital resources
11. Citation theory	11. Bibliometric models and distributions
12. Communication theory	12. Structured abstracts (academic writing)

categories. The categories reflecting clusters of work in the two studies, as labeled by the authors, are shown in Table 1.

Some of the areas in the three examples remain the same over time, showing an overall stability of general interests and foci of information science from its emergence to this day. The three areas of major and continuing interest are *information retrieval*, *user and use studies*, and *metric studies*. They correspond to the Three Big Questions for information science listed at the start of this section. Naturally, the variety and type of work in these three areas has changed and evolved over time, as elaborated below, but the general thrust and emphasis stayed stable.

Some areas have disappeared. The interest in the functioning of abstracting and indexing services, specialized information centers, and the responsibilities of different agencies for improved information services, so prominent in the 1959 Proceedings, are not prominent at all in later periods. Online Public Access Catalogs (OPACs) were prominent as an area cluster in the period 1971–1995 but did not appear in the 1996–2005 period; research in this area waned. The same holds for general library systems, covering library automation; the area was prominent during 1971–1995, but not anymore. The field had a prominent area of imported ideas between 1971–1995, covering the deliberations of adaptation and the application of various theories from information theory (Shannon), sociology (Merton), and other fields, but not anymore. Theory importing is not a major area any longer in information science. However, there is a significant exception. A major trend is evident in the incorporation of ideas, theories, and methods from the social sciences into many studies related to human information behavior to such an extent that they are not considered as imported any more.

In the Web age, covering the period 1996–2005, new areas have appeared. Not surprisingly, one of them is webometrics, extending the metric studies to the Web. Another new area is the visualization of knowledge domains, providing a new method of presenting retrieval processes and results and also extending citation and metric analyses.

The intellectual structure of information science also covers two camps of authors concentrating in different areas. White and McCain called them “retrieval people” and “literature people.”^[7] The first group congregates in the area of information retrieval; the second in the area of human information behavior and metric studies. They represent two broad branches of information science, one system-oriented and the other user-oriented. They are relatively isolated from each other. In the words of White and McCain again: “As it turns out, information science looks rather like Australia: Heavily coastal in its development, with a sparsely settled interior.” The relative isolation is conceived as unproductive for all areas. There were a number of calls for collaboration, some quite impatient, and a few efforts at actually bridging the gap, but the gap has yet to be effectively bridged.

INFORMATION RETRIEVAL

Considering the Three Big Questions for information science, stated above, this section addresses the design question: *How can access to recorded information be made most rapid and effective?* The area is concentrated on systems and technology.

Right after the Second World War a variety of projects started applying a variety of technologies to the problem of controlling information explosion, particularly in

science and technology. In the beginning the technologies were punched cards and microfilm, but soon after computers became available the technology shifted to, and stayed with, computers. Originally, many activities involved specific fields of application, such as chemistry. By the mid-1960s computer science joined the efforts in a big way.

Various names were applied to these efforts, such as “*machine literature searching*,” or “*mechanical organization of knowledge*” but by the mid-1950s “*information retrieval*” prevailed. Actually, the term “*information retrieval*” (IR) was coined by mathematician and physicist Calvin N. Mooers (1919–1994), a computing and IR pioneer, just as the activity started to expand from its beginnings after Second World War. He posited that

Information retrieval is . . . the finding or discovery process with respect to stored information . . . useful to [a user]. Information retrieval embraces the intellectual aspects of the description of information and its specification for search, and also whatever systems, technique, or machines that are employed to carry out the operation.^[9]

Over the next half century, information retrieval evolved and expanded widely. In the beginning IR was static. Now it is highly interactive. Earlier it dealt only with representations—indexes, abstracts—now it deals with full texts as well. It concentrated on print only, now it covers every medium, . . . , and so on. Advances in the field are impressive, now covering the Web, and still go on. Contemporary search engines are about information retrieval. But in a basic sense, IR still continues to concentrate on the same fundamental things Mooers described. Searching was and still is about retrieval of relevant (useful) information or information objects.

It is of interest to note what made IR different, compared to many other techniques, applied to the control of information records over a long period of time. The key difference between IR and related methods and systems that long preceded it—such as classifications, subject headings, various indexing methods, or bibliographic descriptions, including the contemporary Functional Requirements for Bibliographic Records—is that IR specifically included “specification for search.” The others did not. Since the days of the pioneers in bibliographic organization in the United States, Charles Ammi Cutter (1837–1903) and Melvil Dewey (1851–1931), the emphasis was on the creation of systems for bibliographic representation and control. In these long-standing techniques, what users’ needs are and should be fulfilled was specified in detail. Following that, the representation of information objects was also prescribed in detail. In other words, data about information objects (books, articles, etc.) in bibliographic records are organized in a way to fulfill the specified needs. However, how the search ought to be done was not specified or addressed at all. Searching was

assumed and left to itself—it just happens. In IR, users’ needs are assumed as well, but the search process is specified in algorithmic detail and data is organized to enable the search. Search engines are about searching to start with; everything else is subsumed to that function.

Relevance

The fundamental notion used in bibliographic description and in all types of classification or categorization, including those used in contemporary databases, is *aboutness*. Cataloging and classification describe what the documents were all about with an implied idea that *about*, among others, may facilitate searching. Machine Readable Cataloging (MARC) that was developed by Henriette Avram (1919–2006) at the Library of Congress beginning in the 1960s follows the same principle. Online Public Access Catalogs (OPACs) that emerged more than a decade later are based on MARC. They include various search mechanisms, but are relatively difficult and ineffective as search tools. While implying searching *aboutness* does not really facilitate it.

The fundamental notion used in IR is *relevance*. Retrieval is not about any kind of information, and there are a great many, but about *relevant* information (or as Mooers called it *useful to a user* or Bush *momentarily important*). Basically, relevant information is that which pertains to the matter or problem at hand. Fundamentally, bibliographic description and classification concentrate on describing and categorizing information objects. IR is also about that, but in addition IR is about searching, and searching is about relevance. Very often, the differences between databases and IR are discussed in terms of differences between structured and unstructured data, which is OK, but the fundamental difference is in the basic notion used: *aboutness* in the former and *relevance* in the latter. The two notions are not at all equivalent. Relevance entered as a basic notion through the specific concentration on searching. True, searching for relevant information precedes IR by centuries, if not millennia, but in IR the process was adapted as primary orientation.

By choosing relevance as a basic, underlying notion of IR, related information systems, services, and activities—and with it, the whole field of information science—went in a direction that differed from approaches taken in librarianship, documentation, and related information services, and even in expert systems and contemporary databases in computer science.

In this sense, information science is on the one hand connected to relevance and on the other hand to technologies and techniques that enhance probability of the retrieval of relevant and the suppression of nonrelevant information. Relevance, as a basic notion in information science, is a human notion, widely understood in similar ways from one end of the globe to the other. This affected the widespread acceptance of information retrieval

techniques globally. However, relevance, and with it information retrieval, involves a number of complexities: linguistic, cognitive, psychological, social, and technological, requiring different solutions. But the basic idea that searching is for relevant information does not.

As mentioned, relevance is a human notion. In human applications, relevance judgments exhibit inconsistencies, situational and dynamic changes, differences in cognitive interpretations and criteria, and other untidy properties common to human notions. This stimulated theoretical and experimental investigations about the notion and applications of relevance in information science. The experiments, mostly connected to relevance judgments and clues (what affected the judgments, what are people using in judgments) started already in the 1960s and continue to this day. The idea was and still is that findings may affect development of more effective retrieval algorithms. This is still more of a goal; actual translations from research results to development and practical applications were meager, if attempted at all.

Algorithms

IR systems and techniques, no matter in what form and including contemporary search engines, are geared toward retrieval of relevant information. To achieve that they use algorithms—logical step-by-step procedures—for the organization, searching, and retrieval of information and information objects. Contemporary algorithms are complex and in a never-ending process of improvement, but they started simple and still incorporate those simple roots.

The first and simple algorithm (although at the time it was not called that) applied in the 1940s and early 1950s was aimed at searching and retrieving from edge-notched punch cards using the operation of Boolean algebra. In the early 1950s Mortimer Taube (1910–1965), another IR pioneer and entrepreneur, founded a company named Documentation Inc. devoted to the development and operation of systems for the organization and retrieval of scientific and technical information. Taube broke away from the then-standard methods of subject headings and classification, by developing Uniterms and coordinate indexing. Uniterms were keywords extracted from documents; a card for a given Uniterm listed the documents that were indexed by that Uniterm. Coordinate indexing was actually a search and retrieval method for comparing (coordinating) document numbers appearing on different Uniterm cards by using a logical AND, OR, or NOT operation. Although at the time the algorithm was not recognized as Boolean algebra by name, the operation was in effect the first application of a Boolean algorithm for information retrieval. Uniterms and coordinate indexing were controversial for a time but soon it was recognized that the technique was a natural for use as a base for computerized search and retrieval. All IR systems built in the next few

decades incorporated Boolean algebra as a search algorithm and most have it under the hood today, along with other algorithms. All search engines offer, among others, Boolean search capabilities.

At the start of IR, and for a long time to come, the input—indexes and abstracts in particular—was constructed manually. Professionals indexed, abstracted, classified, and assigned other identifiers to information objects in a variety of fields. Input was manual; output—searching—was automated. Big online systems and databases, such as Medline and Dialog, which came about respectively in 1971 and 1972 and operate to this day, were based on that paradigm. Efforts to automate input, as well, commenced in the 1950s by the development of various algorithms for handling of texts. They took much longer to be developed and adopted more operationally than searching algorithms—the problem was and still is much tougher.

Hans Peter Luhn (1896–1964) a prodigious inventor with a broad range of patents joined IBM in 1941 and became a pioneer in development of computerized methods for handling texts and other IR methods in the 1950s. Luhn pioneered many of the basic techniques now common to IR in general. Among others, he invented the automatic production of indexes from titles and texts—Key Words in Context or KWIC indexing that lead to automatic indexing from full texts; automatic abstracting that lead to summarization efforts; and Selective Dissemination of Information (SDI) to provide current awareness services that led to a number of variations, including today's RSS (Really Simple Syndication). The demonstration of automatic KWIC indexing was the sensation at the aforementioned 1959 International Conference on Scientific Information.

Luhn's basic idea to use various properties of texts, including statistical ones, was critical in opening the handling of input by computers for IR. Automatic input joined the already automated output. Of course, Luhn was not the only one who addressed the problems of deriving representations from full texts. In the same period of the 1950s for instance, Phyllis Baxendale developed methods of linguistic analysis for automatic phrase detection and syntactic manipulations and Eugene Garfield was among the first, if not even the first, to join automated input and output in an operational system, that of citation indexing and searching.

Further advances that eventually defined modern IR came about in the 1960s. Statistical properties of texts—frequency and distribution of words in individual documents and in a corpus or collection of documents—were expressed in terms of probabilities that allowed for a variety of algorithms not only to extract index terms, but also to indicate term relations, distances, and clusters. The relations are inferred by probability or degree of certainty. They are inductive not deductive. The assumption, traced to Luhn, was that frequency data can be used to extract

significant words to represent the content of a document and the relation among words. The goal was to find a match between queries and potentially relevant documents, based on a probability of documents being relevant. Once expressed in terms of probabilities, documents can be ranked from those that have a higher probability to those that have a lower probability of a match. There are many methods for doing this. The basic plan was to search for underlying mathematical structures to guide computation. These were powerful ideas that led to an ever-expanding array of new and improved algorithms for indexing and other information organization methods, along with the associated search and retrieval. Moreover, they lend themselves to experimentation.

A towering figure in advancing experimentation with algorithms for IR was Gerard (Gerry) Salton (1927–1995), a computer scientist and academic (Harvard and Cornell Universities) who firmly connected IR with computer science. Within a framework of a laboratory he established, (entitled the SMART project) Salton and collaborators, mostly his students, ran IR experiments from the mid-1960s to the time of his death in 1995. Many new IR algorithms and approaches were developed and tested; they inspired practical IR developments and further IR research in many countries around the world. Many of his students became leaders in the IR community. Salton was very active nationally and internationally in the promotion of IR; he is the founder of the Special Interest Group on Information Retrieval (SIGIR) of the Association of Computing Machinery (ACM). SIGIR became the preeminent international organization in IR with annual conferences that are the main event for reporting advances in IR research. As a result of global interest in IR, these conferences now alternate between continents. While Salton's research group started in the United States, today many similar groups operate in academic and commercial environments around the globe.

Contemporary IR has spread to many domains. Originally, IR concentrated on texts. This has expanded to any and all other media. Now there are research and pragmatic efforts devoted to IR in music, spoken words, video, still and moving images, and multimedia. While originally IR was monolingual, now many efforts are devoted to cross-lingual IR (CLIR). Other efforts include IR connected with Extensible Markup Language (XML), software reuse, restriction to novelty, adversarial conditions, social tagging, and a number of special applications.

With the appearance and rapid growth of the Web starting in the mid-1990s many new applications or adaptations of IR sprouted, as well. The most prominent are search engines. While a few large search engines dominate the scene globally, practically, there is no nation that does not have its own versions tailored to its own populace and interests. While practical IR was always connected with commercial concerns and information industry, the appearance, massive deployment and use of search

engines pushed IR into a major role commercially, politically, and socially. It produced another effect, as well. Most, if not all, search engines use many well-known IR algorithms and techniques. But many search engines, particularly the major ones, in addition have developed and deployed their own IR algorithms and techniques, not known in detail and not shared with the IR community. They support aggressive efforts in IR research and development, mostly in-house. Contemporary IR also includes a proprietary branch, like many other industries.

Testing

Very soon after IR systems appeared, a number of claims and counterclaims were made about the superiority of various IR methods and systems, without supporting evidence. In response, the perennial questions asked of all systems were raised: *What is the effectiveness and performance of given IR approaches? How do they compare?* It is not surprising that these questions were raised in IR. At the time; most developers, funders, and users associated with IR were engineers, scientists, or worked in related areas where the question of testing was natural, even obligatory.

By the mid-1950s suggestions for two measures for evaluation of effectiveness of IR systems were made; they were precision and recall. Precision measures how many of *retrieved* items (let's say documents) were relevant or conversely how many were noise. Recall measures how many of the *potentially relevant items in a given file or system* were actually retrieved, or conversely how many were not retrieved even though they were relevant. The measures were widely adopted and used in most evaluation efforts since. Even today, the two measures, with some variation, are at the base for evaluation of the effectiveness of output using given retrieval algorithms and systems. It is significant to note that the two measures are based on the comparison of human (user or user surrogate) judgments of relevance with IR algorithms' or systems' retrieval of what it considered as relevant, where human judgment is the gold standard.

A pioneer in IR testing was Cyril Cleverdon (1914–1997), a librarian at the Cranfield Institute of Technology (now Cranfield University) in the United Kingdom. From the late-1950s until the mid-1970s Cleverdon conducted a series of IR tests under the name “Cranfield tests.” Most famous were the tests sponsored by the (U.S.) National Science Foundation from 1961 to 1966 that established a model of IR systems (the so-called traditional model that concentrates on query on the one end and matched with static retrieval from an IR system or algorithm on the other end), and a methodology for testing that is still in use. One of the significant and surprising finding from Cranfield tests was that uncontrolled vocabularies based on natural language (such as keywords picked by a computer algorithm) achieve retrieval effectiveness comparable to

vocabularies with elaborate controls (such as those using thesaurus, descriptors, or classification assigned by indexers). The findings, as expected, drew skepticism and strong critique, but were confirmed later by Salton and others. Not surprisingly these conclusions caused a huge controversy. But they also provided recognition of automatic indexing as an effective approach to IR.

Salton coupled development of IR algorithms and approaches with testing; he enlarged on Cranfield approaches and reaches. Everything that Salton and his group proposed and developed was mandatorily tested. The norm was established: No new algorithms or approaches were accepted without testing. In other words, testing became mandatory for any and all efforts that propose new algorithms and methods. It became synonymous with experimentation in IR.

After Salton, contemporary IR tests and experiments are conducted under the umbrella of the Text REtrieval Conference (TREC). TREC, started in 1992 and continuing to date, is a long-term effort at the (U.S.) National Institute for Standards and Technology (NIST), that brings various IR teams together annually to compare results from different IR approaches under laboratory conditions. Over the years, hundreds of teams from dozens of countries participated in TREC covering a large number of topics. TREC is dynamic: As areas of IR research change, so do the topics in TREC. Results are at the forefront of IR research.^[10]

In many respects, IR is the main activity in information science. It has proved to be a dynamic and ever-growing area of research, development, and practice, with strong commercial interest and global use. Rigorous adherence to testing contributed to the maturing of information retrieval.

HUMAN INFORMATION BEHAVIOR

Considering the Three Big Questions for information science, stated above, this section addresses the social and individual question: *How do people relate to, seek and use information?* While often connected with systems, the emphasis in this area of information science is on people rather than systems.

Human information behavior refers to a wide range of processes which people employ when engaged with information and to related cognitive and social states and effects. In his book that comprehensively covers research on information behavior (with over 1100 documents cited, most since 1980), Case defines that information behavior:

“encompasses information seeking as well as the totality of other *unintentional* or *passive* behaviors (such as glimpsing or encountering information), as well as purposive behaviors that do not involve seeking, such as actively *avoiding* information [11, p. 5]. (emphasis in the original).

As can be imagined, human information behavior, as with many other human behaviors, is complex, not fully understood, and of interest in a number of fields. A great many studies and a number of theories address various aspects related to human information behavior in psychology, cognitive science, brain sciences, communication, sociology, philosophy and related fields, at times using different terminology and classifications. Under various names, scholarly curiosity about human information behavior is longstanding, going back to antiquity.

Of particular interest in information science are processes, states, and effects that involve *information needs and use* and *information seeking and searching*. The order in which these two major areas of human information behavior studies are listed represents their historic emergence and emphasis over time.

Historically, the study of information needs and use preceded information science. Many relevant studies were done during the 1930s and 1940s in librarianship, communication, and specific fields, such as chemistry, concentrating on use of sources, media, systems, and channels. Already by the 1950s this area of study was well developed in information science—for instance, the aforementioned 1959 *Proceedings of the International Conference on Scientific Information*^[3] had a whole area with a number of papers devoted to the topic. The *Annual Review of Information Science and Technology* had regular annual chapters on “information needs and use” starting with the first volume in 1966 and ongoing through 1978. Thereafter, chapters covering this area were broadened to cover in addition various aspects or contexts of information behavior, including information seeking. This change illustrates how the emphasis in topics studied significantly changed over time. Studies in human information behavior are evolving and slowly maturing.

Information Needs and Use

Over the years “information needs and use” was used as a phrase. However, while related information need and information use are distinct concepts. *Information need* refers to a cognitive or even a social state and *information use* to a process.

For decades, *information need* was used as a primitive concept on two levels: on an individual level it signified a cognitive state which underlies questions posed to information systems and requests for information in general; on a social level it signified information required for functioning and keeping abreast of a whole group, such as chemists. On the first, or cognitive, level it was assumed that individuals ask questions and request information because of a recognition that the knowledge one has is inadequate for a given problem or situation; it is subjective as represented by individuals; it is in the head of a user. On the second, or social, level it was assumed that a social group with common characteristics, goals, or tasks shares

common information requirements that may be satisfied by specific information sources; it is more objective as determined by a group of individuals on the basis of some consensus or by experts based on experience. In general, information need was considered as instrumental in reaching a desired informational goal.

The concept of *information need* was entrenched until the start of the 1980s. Slowly, critiques of the concept gained ground by pointing out that it is nebulous, as are most other “need” concepts in every field where they are used; that it is often substituted for “information demand,” which is a very different process and not a state; that it is associated with behaviorism, which in itself fell out of favor; that it is a subjective experience in the mind of a person and therefore not accessible for observation; and that it ignores wider social aspects and realities. Moreover, underlying assumptions were challenged. By the end of the decade information need was largely abandoned as a subject of study or explanation of underlying information processes. Instead, studies of information seeking and other aspects of information behavior gained ground. However, information need is still represented in the traditional IR model (mentioned above) as the source of questions that are submitted to retrieval systems. It is not further elaborated in that framework, just listed as a primitive concept.

The concept of *information use* is more precise and it is operationally observable. Studies of information use were done for a long time and in many fields. For instance, use of libraries or use of literature in a given area was investigated long before information science emerged and before information use became one of the major topics of information science research. In information science, information use refers to a process in which information, information objects, or information channels are drawn on by information users for whatever informational purpose. The process is goal-directed. Questions are asked: *Who are the users of a given information system or resource? What information objects do they use? What information channels are used to gather information?* Or in other words: *Who uses what? How? For what purpose?*

The studies addressing these questions were, and still are, pragmatic, retrospective, and descriptive. Historically, as they emerged in the early 1950s, they were directed toward fields and users in science and technology. This is not surprising. As mentioned, information science emerged as a response to the problem of information explosion in science and technology thus the use studies were in those areas. Regarding topics, many early studies addressed users’ distribution of time and resources over different kinds of documents: scientific journals, books, patents, abstracting and indexing services, and so on. As the realm of information science expanded to cover other areas and populations, use studies expanded their coverage as well. By the 1990s, studies emerged that also covered information use in many populations and activities, including the small worlds of everyday living.

The early motivation for user studies was pragmatic: to discover guidelines for the improvement of practice. This was of great concern to practitioners, and consequently most such studies were done by practitioners. By 1970 or so there was a move toward academic studies of information use motivated by a desire to understand the process better and provide models and theories. By 2008 there are still two worlds of user studies: one more pragmatic, but now with the goal of providing the basis for designing more effective and usable contemporary IR and Web systems, including search engines, and the other more academic, still with the goal of expanding understanding and providing more plausible theories and models. The two worlds do not interact well.

Information Seeking and Searching

Information seeking refers to a set of processes and strategies dynamically employed by people in their quest for and pursuit of information. Information seeking also refers to the progression of stages in those processes. In the majority of theories and investigations about information seeking, the processes are assumed to be goal directed. In his aforementioned book, Case defines information seeking as

“a conscious effort to acquire information in response to a need or gap in your knowledge.” [11], p. 5]

Not surprisingly, information seeking is of interest in a number of fields from psychology, sociology, and political science to specific disciplines and professions, often under different names and classifications, such as information gathering or information foraging. The literature on the theme is large, spanning many decades. Historically, information-seeking concerns and studies in information science emerged by the late 1970s in academic rather than pragmatic environments. Only lately have they turned toward pragmatic concerns, as well. It was recognized that information use was the end process, preceded by quite different, elaborate, and most importantly, dynamic behavior and processes not well understood. The studies began in large part by trying to observe and explain what people do when they search and retrieve information from various retrieval systems, to expand fast to involving a number of different contexts, sources—formal and informal—and situations or tasks. The dynamic nature of information-seeking became the prime focus in observations, experiments, models, and theories. Questions are asked: *What do people actually do when they are in a quest for and pursuit of information? How are they going about and how are they changing paths as they go about? What are they going through on a personal level? What information channels are used to gather information? How?*

Information seeking, as is the case with most human information behavior, is highly dependent on context.

While context may be everything, the very concept of context is ill defined, or taken as primitive and not defined. The contexts may involve various motivations for information seeking, various cognitive and affective states, various social, cultural, or organizational environments, various demographic characteristics, values, ways of life, and so on. A number of information-seeking studies were indeed directed toward various contexts. Thus, there is a wide range of such studies regarding context, accompanied by difficulties toward generalization.

To deal with more defined contexts, and enable specific observation, task-oriented information-seeking studies emerged in the 1990s. And they are going strong up to this day. Task studies deal with specific goals, mostly related to assignments in defined circumstances, time periods, or degree of difficulty. They represent a step in the ongoing evolution, not only of information-seeking studies in particular but also in information behavior research in general. By the 2000s we also see the emergence of studies in collaborating behaviors, also related to given tasks.

Information searching is a subset of information seeking, and in the context of information science, it refers to processes used for interrogating different information systems and channels in order to retrieve information. It is the most empirical and pragmatic part of information-seeking studies. Originally, search studies concentrated on observation and modeling of processes in the interrogation of IR systems. With the advent of digital environments, the focus shifted toward Web searching by Web users. New observational and experimental methods emerged, becoming a part of exploding Web research. Such search studies have a strong pragmatic orientation in that many are oriented toward improving search engines and interfaces, and enhancing human–computer interactions.

Models and Theories

The research area and accompanying literature of information behavior in information science is strong on models and theories. It follows a tradition and direction of such research in many other disciplines, particularly psychology, communication, and philosophy. Being primarily pragmatic and retrospective, information use studies were not a great source for models and theories. In contrast, broader studies of information behavior, and particularly of information seeking, are brimming with them. Numerous models and theories emerged, some with more, others with less staying power. The extent of this work is exemplified in a compilation *Theories of Information Behavior*,^[12] where some 70 different (or differing) theories and models are synthesized. To illustrate, we should sample three well-known theories, each in one of the three areas of human information behavior described above. Each of them is widely accepted and cited, and tested, as well.

What is behind an information need? Why do people seek information in the first place? Starting in late 1970s and for the next two decades or so, Nicholas Belkin and his colleagues addressed this question by considering that the basic motivation for seeking information is what they called “anomalous state of knowledge” (ASK), thus the “ASK theory,” or as they called it, “ASK hypothesis” (described among others in Belkin, Oddy, and Brooks).^[13] Explicitly following a cognitive viewpoint, they suggest that the reason for initiating an information-seeking process could be best understood at the cognitive level, as a user (information seeker) recognizes that the state of his/her knowledge is in some way inadequate (anomalous) with respect to the ability to resolve a problematic situation and achieve some goal. Anomaly was used explicitly, not only to indicate inadequacy due to lack of knowledge, but also due to other problems, such as uncertainty of application to a given problem or situation. ASK theory is an attempt to provide an explicit cognitive explanation of information need or gap by proposing specific reasons why people engage in information seeking. It also suggests that anomalous states could be of different types. One of the strengths of ASK theory is that, unlike many other similar theories, it was successfully tested in a few experiments. One of the weaknesses is that it rests solely on a cognitive basis, using the problem or situation toward which the whole process is oriented as a primitive term.

What is behind the information search process? How is it constructed? Carol Collier Kuhlthau addressed these questions in a series of empirically grounded studies through a period of some 20 years starting in the early 1980s.^[14] Her model and theory, called the Kuhlthau Information Search Model, provides a conceptual and relatively detailed framework of the information-seeking and search process. It is based on the personal construct theory in psychology that views learning as a process of testing constructs; consequently it views the search as a dynamic process of progressive construction. The model describes common patterns in the process of information seeking for complex tasks that have a discrete beginning and ending over time and that require construction and learning. The innovative part of the model is that it integrates thoughts, feelings, and actions in a set of stages from initiation to presentation of the search process. Not only cognitive, but also affective aspects, such as uncertainty connected with anxiety, are brought in the explanation of the process. The work started within learning context in schools, continued with a series of longitudinal studies, and moved on to a series of case studies in a number of fields. The strength of the model is that it incorporates affective factors that play a great role not only in searching but in human information behavior at large; furthermore it was extensively verified and revised over time. The weakness is that its educational roots are still recognizable—many search processes have different goals and contexts, thus the model may not fit.

What types of activities are involved in information seeking in general and information retrieval searching in particular? What is the relation between different activities? Starting in the mid-1980s and continuing for close to two decades, David Ellis and his colleagues addressed these questions in a series of empirical studies that led to the formulation and continuing refinement of a model known as Ellis's Model of Information-Seeking Behavior, primarily oriented toward behavior in information retrieval.^[15] The model is based on a theoretical premise that the study of behavior presents a more tractable and observable focus for study than cognitive approaches. Consequently, its base is behavioral rather than cognitive. The model incorporates a premise that the complex process of information seeking, particularly as related to information retrieval, rests on a relatively small and finite number of different types of interacting activities, these include starting, chaining, browsing, differentiating, monitoring, and extracting. The explicit goal of studies associated with Ellis' model was pragmatic: to inform design and operations of IR systems. The strength of the model is in the reduction of a complex process to a relatively small set of distinct and dynamically interacting processes. The weakness is that it does not address cognitive and affective aspects, shown to be of importance.

The three models can be considered also as theories of information behavior. In turn, each of them is based on a different approach and theory. The first one is related to cognition as treated in cognitive science, the second to personal construct theory in psychology, and the third to behaviorism in psychology. This illustrates different approaches and multidisciplinary connections of human information behavior studies in information science. As yet, they have not found a common ground.

METRICS

Considering the Three Big Questions for information science, stated above, this section addresses the physical question: *What are the features and laws of the recorded information universe?* While often connected with systems, the emphasis in this area of information science is on information objects or artifacts rather than systems; these are the content of the systems. It is about characterizing content objects.

Metrics, such as econometrics, biometrics, sociometrics, etc., are important components in many fields; they deal with statistical properties, relations, and principles of a variety of entities in their domain. Metric studies in information science follow these by concentrating on statistical properties and the discovery of associated relations and principles of information objects, structures, and processes. The goals of metric studies in information science, as in other fields, are to characterize statistically entities under study and more ambitiously to discover regularities

and relations in their distributions and dynamics in order to observe predictive regularities and formulate laws.

The metric studies in information science concentrate on a number of different entities. To denote a given entity under study over time, these studies were labeled by different names. The oldest and most widely used is *bibliometrics*—the quantitative study of the properties of literature, or more specifically of documents, and document-related processes. Bibliometric studies in information science emerged in the 1950s right after the start of the field. *Scientometrics*, which came about in the 1960s, refers to bibliometric and other metric studies specifically concentrating on science. *Informetrics*, emerging in the 1990s, refers to the quantitative study of properties of all kinds of information entities in addition to documents, subsuming bibliometrics. *Webometrics*, which came about at the end of the 1990s, concentrates, as the name implies, on Web-related entities. *e-Metrics*, which emerged around 2000, are measures of electronic resources, particularly in libraries.

Studies that preceded bibliometrics in information science emerged in the 1920s and 1930s; they were related to authors and literature in science and technology. A number of studies went beyond reporting statistical distributions, concentrating on relations between a quantity and the related yield of entities under study. Here are two significant studies that subsequently greatly affected development of bibliometrics. In the 1920s, Alfred Lotka (1880–1949, American mathematician, chemist, and statistician) reported on the distribution of productivity of authors in chemistry and physics in terms of articles published. He found a regular pattern where a large proportion of the total literature is actually produced by a small proportion of the total number of authors, falling down in a regular pattern, where the majority of authors produce but one paper—after generalization this became known as Lotka's law. In the 1930s, Samuel Bradford (1878–1948, British mathematician and librarian), using relatively complete subject bibliographies, studied the scatter of articles relevant to a subject among journals. He found that a small number of journals produce a large proportion of articles on the subject and that the distribution falls regularly to a point where a large number of journals produce but one article on the same subject—after generalization this became known as Bradford's law or Bradford's distribution. Similar quantity-yield patterns were found in a number of fields and are generally known as Pareto distributions (after Italian economist Vilfredo Pareto, 1848–1923). Lotka's and Bradford's distributions were confirmed many times over in subsequent bibliometric studies starting in the 1950s. They inspired further study and moreover set a general approach in bibliometric studies that was followed for decades.

Data Sources

All metric studies start from and depend on data sources from which statistics can be extracted. Originally, Lotka

used, among others, Chemical Abstracts, and Bradford used bibliographies in applied geophysics and in lubrication. These were printed sources and analysis was manual. For a great many years, the same kind of print sources and manual analysis methods were used.

The advent of digital technology vastly changed the range of sources, as well as significantly enlarged the type and method of analysis in bibliometrics, or as Thelwall put it, in a historical synthesis of the topic, “bibliometrics has changed out of all recognition since 1958.”^[16] This is primarily because sources of data for bibliometric analyses proliferated (and keep proliferating), inviting new analysis methods and uses of results.

In 1960 Eugene Garfield (U.S. chemist, information scientist, and entrepreneur) established the Institute for Scientific Information (ISI), which became a major innovative company in the creation of a number of information tools and in bibliometric research. In 1964, ISI started publishing the *Science Citation Index*, created by use of computers. Citation indexes in social sciences and in art and humanities followed. While citation indexes in various subjects, law in particular, existed long before Garfield applied them in science, the way they were produced and used was innovative. Besides being a commercial product, citation indexes became a major data source for bibliometric research. They revolutionized bibliometrics.

In addition to publication sources—journal articles and citations—de Solla Price pioneered the use of a range of statistics from science records, economics, social sciences, history, international reports, and other sources to derive generalizations about the growth of science and the factors that affected information explosion.^[5] Use of diverse sources became a trademark of scientometrics.

As the Web became the fastest growing and spreading technology in history it also became a new source of data for ever-growing types of bibliometric-like analyses, organized under the common name of webometrics. The Web has a number of unique entities that can be statistically analyzed, such as links, which have dynamic distributions and behavior. Thus, webometrics started covering quite different grounds.

As more and more publications, particularly journals and more recently books, became digital they also became a rich source for bibliometric analyses. Libraries and other institutions are incorporating these digital resources in their collections, providing a way for various analyses of their use and other aspects. Most recently, digital libraries became a new source of analysis for they are producing massive evidence of the usage patterns of library contents, such as journal articles, for the first time. Thus, the emergence of e-metrics.

[From now on all the metric studies in information science (bibliometrics, scientometrics, informetrics, webometrics, and e-metrics) for brevity will be collectively referred to as *bibliometrics*.]

In the digital age, sources for bibliometric analyses are becoming more diversified, complex, and richer. They have become a challenge for developing new methods and refining existing methods and types of analysis.

Types and Application of Results

Lotka showed distribution of publication regarding authors and Bradford distribution of articles regarding journals. In seeking generalization, both formulated respective numerical distributions in a mathematical form. The generalizations sought a scientific law-like predictive power, with full realization that social science laws are not at all like natural science laws. In turn, mathematical expressions of Lotka's and Bradford's laws were refined, enlarged, and corrected in numerous subsequent mathematical papers; the process is still going on. This set the stage for the development of a branch of bibliometrics that is heavily mathematical and theoretical; it is still growing and continuously encompassing new entities and relations as data becomes available. Bradford also illustrated the results graphically. This set the stage for the development of visualization methods for showing distributions and relations; the efforts evolved to become quite sophisticated using the latest methods and tools for data visualization to show patterns and structures.

Over the years bibliometric studies showed many features of the ever-growing number of entities related to information. Some were already mentioned, here is a sample of others: frequency and distribution analysis of words; cowords; citations; cocitations; emails; links; etc., and quite a few others.

Until the appearance of citation indexes, bibliometric studies in information science were geared to analysis of relations; many present studies continue with the same purpose and are geared toward relational applications. But with the appearance of citation data, a second application emerged: evaluative.^[16]

Relational applications seek to explicate relationships that are results of research. Examples are emergence of research fronts; institutional, national, and international authorship productivity and patterns; intellectual structure of research fields or domains; and the like.

Evaluative applications seek to assess or evaluate the impact of research, or more broadly, scholarly work in general. Examples are use of citations in promotion and tenure deliberations; ranking or comparison of scholarly productivity; relative contribution of individuals, groups, institutions, or nations; relative standing of journals; and the like.

Evaluative indicators were developed to numerically express the impact of given entities. Here are two of the most widely used indicators. The first deals with journals, the second with authors. *Journal Impact Factor*, devised in the 1960s by Garfield and his colleagues, provides a numerical value to how often a given journal is included

in citations in all journals over a given period of time, normalized for the number of articles appearing in a journal. Originally, it was developed as a tool to help selection of journals in *Science Citation Index* but it morphed into a widely used tool for ranking and comparing the impact of journals. The second indicator deals with authors. A most influential new indicator of impact is the *h-index* (proposed in 2005 by Jorge Hirsh, a U.S. physicist). It quantifies and unifies both an author's scientific productivity (number of papers published by an author) and the apparent scientific impact of a scientist (number of citations received)—it unifies how much was published with how much was cited. Both of the indices are continuously discussed, mathematically elaborated, and criticized.

Evaluative studies are controversial at times. By and large, evaluative applications rest on citations. The central assumption here is that citation counts can be used as an indicator of value because the most influential works are most frequently cited. This assumption is questioned at times, thus it is at the heart of controversies and skepticism about evaluative approaches.

Evaluative applications are used at times in support of decisions related to tenure and promotion processes; academic performance evaluations of individuals and units in universities; periodic national research evaluations; grant applications; direction of research funding; support for journals; setting science policies; and other decisions involving science. Several countries have procedures in place that mandate bibliometric indicators for the evaluation of scientific activities, education, and institutions. They are also used in the search of factors influencing excellence.

The current and widening range of bibliometric studies is furthering understanding of a number of scholarly activities, structures, and communication processes. They are involved in the measuring and mapping of science. In addition, they have a serious impact on evaluation, policy formulation, and decision making in a number of areas outside of information science.

DIGITAL LIBRARIES

Long before digital libraries emerged in the mid-1990s, J. C. R. Licklider (1915–1990, U.S. computer scientist) in a prescient 1965 book *Libraries of the Future* envisioned many of the features of present digital libraries, with some still to come.^[17] While Licklider was a technology enthusiast and formulated his vision of the library in a technological context, he also foresaw the handling of content in cognitive, semantic, and interactive ways.

Many of the components were in place quite some time before they were shaped and unified operationally into digital libraries. For instance, online searching of abstracting and indexing databases; a number of network information services; library automation systems; document structuring

and manipulation procedures based on metadata; digitized documents; human computer interfaces; and others. With the advent of the Web, many of these older components were refined as needed and amalgamated with a number of new ones to form digital libraries as we know them today.

From the outset, people from a number of fields and backgrounds got involved in the development of digital libraries. Thus various conceptions were derived. Two viewpoints crystallized, one more technological the other more organizational. From the first point of view, a digital library is a managed collection of digital information with associated services, accessible over a network. From the second point of view, a digital library is that, but in addition it involves organizations that provide resources to select, structure, and offer intellectual access to collections of digital works for use by defined communities, and to preserve integrity and ensure persistence of collections and services. The first viewpoint comes mostly from computer science and the second from libraries and other organizations that house and provide digital library services. Digital libraries continue this dual orientation, technological and organizational, because, yes, they are indeed completely dependent on technology but by their purpose and functions they are social systems in the first place.

Many organizations other than libraries enthusiastically started developing and operating digital libraries—museums, historical societies, academic departments, governments, professional organizations, publishers, nonprofit organizations, and so on. As a result, digital libraries take many shapes and forms. They involve a variety of contexts, media, and contents. Many are oriented toward a specific subject. Most importantly, they are used by a variety of users and for a variety of uses. Digital libraries are a highly diverse lot.

The wide and constantly increasing diversity of digital libraries and related collections and portals suggest several issues: traditional libraries are not traditional any more, but hybrid and coming in many digital library forms; many new players have entered the arena, particularly in subject areas; and many new types of uses have emerged in addition to the traditional use of libraries. Digital libraries are truly interdisciplinary. Information science was one of the fields that actively participated in digital library formation, development, and research.

Through NSF and other agencies, the U.S. government funded research in digital libraries through Digital Library Initiatives; European Union and other governments funded similar research and development programs. Governmental funding started around 1995 and lasted about a decade. Most of the funding went toward technological aspects and demonstrations. An important by-product of this funding was the creation of a strong international community of digital library researchers from a number of fields, information science included. Here is another by-product often mentioned: Google was initially developed

at Stanford University under an NSF grant in the Digital Library Initiatives program.

From the outset, information science was involved with digital libraries in a number of ways. Professionally, many information scientists work in digital libraries, particularly in relation to their architecture, systems operations, and services. A diverse number of topics were addressed in research covering the whole life-cycle of digital libraries as reflected in numerous reports, journals, proceedings, and books. Here is a sample: development and testing of digital library architecture; development of appropriate metadata; digitization of a variety of media; preservation of digital objects; searching of digital library contents; evaluation of digital libraries; access to digital libraries; security and privacy issues; study of digital libraries as a place and space; study of users, use, and interactions in digital libraries; effect of digital libraries on educational and other social institutions; impact of digital libraries on scholarship and other endeavors; and policy issues. New research topics are coming along at a brisk pace.

The rapid development and widespread deployment of digital libraries became a force that is determining not only the future of libraries but also of many other organizations as social, cultural, and community institutions. It is instrumental in the development of e-science. It is also affecting the direction of information science in that the domain of problems addressed has been significantly enlarged.

EDUCATION

The fact that education is critical for any field is a truism that hardly needs to be stated. Information science education began slowly in the 1950s and 1960s. Two educational models evolved over time and were followed for decades to come: For brevity, they should be referred to as the Shera and Salton models, after those that pioneered them. Both have strengths and weaknesses. A third model is presently emerging, under the label of i-Schools.

Jesse H. Shera (1903–1982, librarian and library educator) was a library school dean at Western Reserve University (later Case Western Reserve) from 1952 to 1970. Among others, he was instrumental in starting the Center for Documentation and Communication Research at the library school there in 1955. The Center was oriented toward research and development in IR. Shortly thereafter, the library school curriculum started to include courses such as “machine literature searching” (later to become “information retrieval”), and a few other more advanced courses and laboratories on the topics of research in the Center. The basic approach was to append those courses, mostly as electives, to the existing library school curriculum, without modifications of the curriculum as a whole, and particularly not the required core courses. Information science (or information retrieval)

became one of the specialty areas of library science. The base or core courses that students were taking rested in the traditional library curriculum. Information science education was an appendage to library science. Library schools in the United States and in many other countries imitated Shera’s model. They used the same approach and started incorporating information science courses in their existing curriculum as a specialty.

The strength of the Shera model is that it posits education within a service framework, connects the education to professional practice and a broader and user-oriented frame of a number of other information services, and relates it to a great diversity of information resources. The weakness is a lack of a broader theoretical framework, and a lack of teaching of formalism related to systems, such as the development and understanding of algorithms. A majority of researchers in the human information behavior and user-centered approach are associated with this educational environment. Out of this was born the current and widely used designation *library and information science*.

Shera’s model, with contemporary modifications is still the prevalent approach in a majority of schools of library and information science. Some schools evolved to include a major in information science, or reoriented the curriculum toward some of the aspects of information science, or even provided a separate degree. The changes in curricula are accelerating. Dissatisfaction with the model as not in synch with contemporary developments related to information-spurred development of i-Schools discussed below.

Gerard Salton (already mentioned above) was first and foremost a scientist, and a computer scientist at that. As such, he pioneered the incorporation into IR research a whole array of formal and experimental methods from science, as modified for algorithmic and other approaches used so successfully in computer science. His primary orientation was research. For education, he took the time-honored approach of a close involvement with research. The Salton model was a laboratory and research approach to education related to IR. As Shera’s model resulted in information science education being an appendage to library science education, Salton’s model of IR education resulted in being a specialty of and an appendage to computer science education. Computer science students that were already well-grounded in the discipline got involved in SMART and other projects directed by Salton, worked and did research in the laboratory, completed their theses in areas related to IR, and participated in the legendary IR seminars. They also published widely with Salton and with each other and participated with high visibility in national and international conferences. From Harvard and Cornell, his students went to a number of computer science departments where they replicated Salton’s model. Many other computer science departments in the United States and abroad took the same approach. The strength of Salton’s model is that it: (1) starts from a base of a firm grounding in formal mathematical and other methods; and

(2) relates directly to research. The weakness is in that it: (1) ignores the broader aspects of information science, as well as any other disciplines and approaches dealing with the human aspects, that have great relevance to both outcomes of IR research and research itself; and (2) does not incorporate professional practice where these systems are realized and used. It loses users. Consequently, this is a successful, but narrowly concentrated education in IR as a specialty of computer science, rather than in information science. Not surprisingly, the researchers in the systems-centered approach came out of this tradition.

The two educational approaches are completely independent of each other. Neither reflects fully what is going on in the field. While in each model there is an increase in cognizance of the other, there is no educational integration of the systems- and user-centered approaches. The evident strengths that are provided by Shera's and Salton's model are not put together.

The late 1990s and early 2000s saw a movement to broaden and reorient information science education, spearheaded by a number of deans of schools with strong information science educations. Some library and information science schools were renamed into Information Schools or i-Schools. An informal i-School Caucus was formed in 2005. By 2008, the Caucus included over 20 schools quite diverse in origin. They include schools of: information; library and information science; information systems; informatics; public policy and management; information and computer sciences; and computing. The i-Schools are primarily interested in educational and research programs addressing the relationship between information, technology, and people and understanding the role of information in human endeavors. While the i-School movement was originally restricted to the United States, some schools outside the United States are joining. The movement is attracting wide international interest.

The i-Schools represent an innovative, new approach to information science education, with some true interdisciplinary connections. As the millennial decade draws toward an end, it is also signifying a new direction to information science education.

CONCLUSIONS

It was mentioned that information science has two orientations: one that deals with information retrieval techniques and systems and the other that deals with information needs and uses, or more broadly with human information behavior. One is technical and system-oriented, the other individual and social and user-oriented. In pursuing these orientations certain characteristics of the field emerged.

Information science has several general characteristics that are the leitmotif of its evolution and existence. These are shared with many modern fields.

- First, information science is interdisciplinary in nature. However, with various advances, relations with various disciplines are changing over time. The interdisciplinary evolution is far from over.
- Second, information science is inexorably connected to information technology. A technological imperative is compelling and encouraging the evolution of information science, as is the evolution of a number of other fields, and moreover, of the information society as a whole.
- Third, information science is, with many other fields, an active participant in the evolution of the information society. Information science has a strong social and human dimension, above and beyond technology.
- Fourth, while information science has a strong research component that drives advances in the field, it also has an equally strong, if not an even stronger, professional component oriented toward information services in a number of environments. Many innovations come from professionals in the field.
- Fifth, information science is also connected with information industry, a vital, highly diversified, and global branch of the economy.

With accelerating changes in all these characteristics, information science is a field in a constant flux. So are many other fields. The steady aspect is in its general orientation toward information, people, and technology.

Information Search Process (ISP) Model

Carol Collier Kuhlthau

Department of Library and Information Science, Rutgers University, New Brunswick, New Jersey, U.S.A.

Abstract

The information search process (ISP) is a six-stage model of the users' holistic experience in the process of information seeking. The ISP model, based on over two decades of empirical research, identifies three realms of experience: the affective (feelings), the cognitive (thoughts), and the physical (actions) common to each stage. These studies were among the first to investigate the affective aspects or the feelings of a person in the process of information seeking along with the cognitive and physical aspects. Central to the ISP is the notion that uncertainty, both affective and cognitive, increases and decreases in the process of information seeking. A principle of uncertainty for information seeking states that information commonly increases uncertainty in the early stages of the search process. Increased uncertainty indicates a zone of intervention for intermediaries and system designers.

INTRODUCTION

Prior to this research, most studies were constrained by the system's definition of information needs. For the most part, library and information science concentrated on the system's representation of texts rather than on the user's tasks, problems, and processes in information gathering. The classic triad of thoughts, actions, and feelings central to any constructive process had rarely been taken into consideration in study or discussion of information-seeking behavior. Although cognitive processes were increasingly recognized as significant components for understanding information behavior, affective experience continued to be overlooked. There was little or no acknowledgment that the feelings of users may have any import. In the study and understanding of information-seeking behavior, Kuhlthau's work introduced the holistic experience of information seeking from the user's perspective and stressed the important role of affect in information-seeking behavior.

The information search process (ISP) presents a view of information seeking from the user's perspective in six stages: initiation, selection, exploration, formulation, collection, and presentation. The six-stage model of the ISP incorporates three realms of experience: the affective (feelings), the cognitive (thoughts), and the physical (actions) common to each stage.^[1] The ISP reveals information seeking as a process of construction influenced by Kelly's personal construct theory^[2] with information increasing uncertainty in the early stages of the ISP.

The development of the ISP as a conceptual framework is the result of more than two decades of empirical research that began with a qualitative study of secondary school students and the emergence of an initial model, that was verified and refined through various quantitative and longitudinal methods of diverse library users and further

developed in case studies of people in the workplace. To summarize the findings of these studies of the user's perspective of the ISP, the affective symptoms of uncertainty, confusion, and frustration prevalent in the early stages are associated with vague, unclear thoughts about a topic or problem. As knowledge states shifted to clearer, more focused thoughts, a corresponding shift was noted in feelings of increased confidence and certainty. Affective aspects, such as uncertainty and confusion, influenced relevance judgments as much as cognitive aspects, such as personal knowledge and information content. Central in the model of the ISP is uncertainty described formally as a principle of uncertainty for information seeking. Increased uncertainty in the exploration stage of the ISP indicates a zone of intervention for intermediaries and system designers.^[3]

MODEL OF THE ISP

The model of the ISP describes users' experience in the process of information seeking as a series of thoughts, feelings, and actions. Thoughts that begin as uncertain, vague, and ambiguous become clearer, more focused, and specific as the search process progresses. Feelings of anxiety and doubt become more confident and certain. Through their actions, people seek information relevant to the general topic in the beginning stages of the search process and pertinent to the focused topic toward closure. Formulation of a focus or a personal perspective of the topic is a pivotal point in the search process. At that point, feelings shift from uncertain to confident, thoughts change from vague to more clear and interest increases. The model was verified in longitudinal case studies and large-scale studies of diverse samples of library users.^[4,5] Further

studies have examined the implementation of a process approach in education contexts and investigated the ISP in the workplace.^[6]

The ISP describes common experiences in the process of information seeking for a complex task that has a discrete beginning and ending and that requires considerable construction and learning to be accomplished.^[7] The model reveals a search process in which a person is seeking meaning in the course of seeking information. From the user's perspective, the primary objective of information seeking is to accomplish the task that initiated the search, not merely the collection of information as an end in itself. The ISP presents seeking information as a means to accomplish a goal. The model of the ISP is articulated in a holistic view of information seeking from the user's perspective in six stages (Fig. 1):

1. *Initiation*, when a person first becomes aware of a lack of knowledge or understanding and feelings of uncertainty and apprehension are common.
2. *Selection*, when a general area, topic, or problem is identified and initial uncertainty often gives way to a brief sense of optimism and a readiness to begin the search.
3. *Exploration*, when inconsistent, incompatible information is encountered and uncertainty, confusion, and doubt frequently increase and people find themselves "in the dip" of confidence.
4. *Formulation*, when a focused perspective is formed and uncertainty diminishes as confidence begins to increase.
5. *Collection*, when information pertinent to the focused perspective is gathered and uncertainty subsides as interest and involvement deepens.
6. *Presentation*, when the search is completed with a new understanding enabling the person to explain their learning to others or in some way put the learning to use.

In the first stage, *initiation*, a person becomes aware of a gap in knowledge or a lack of understanding, where

feelings of uncertainty and apprehension are common. At this point, the task is merely to recognize a need for information. Thoughts center on contemplating the problem, comprehending the task, and relating the problem to prior experience and personal knowledge. Actions frequently involve discussing possible avenues of approach or topics to pursue.

In the second stage, *selection*, the task is to identify and select the general topic to be investigated and the approach to be pursued. Feelings of uncertainty often give way to optimism after the selection has been made and there is a readiness to begin the search. Thoughts center on weighing prospective topics against the criteria of task requirements, time allotted, personal interest, and information available. The outcome of the possible choices is predicted, and the topic or approach judged to have the greatest potential for success is selected. Typical actions are to confer with others or to make a preliminary search of information available and then to skim and scan for an overview of alternative topics. When, for whatever reason, selection is delayed or postponed, feelings of anxiety are likely to intensify until the choice is made.

The third stage is *exploration* characterized by feelings of confusion, uncertainty, and doubt that frequently increase during this time. The task is to investigate information on the general topic in order to extend personal understanding. Thoughts center on seeking to become oriented and sufficiently informed about the topic to form a focus or a personal point of view. At this stage in the ISP, an inability to express precisely what information is needed can make communication between the user and the system awkward. Actions involve locating information about the general topic, reading to become informed, and relating new information to what is already known. In this stage, the information encountered rarely fits smoothly with previously held constructs, and information from different sources frequently seems inconsistent and incompatible.

Fig. 1 Model of the information search process.
Source: From Kuhlthau.^[7]

People may find the situation quite discouraging and even threatening, causing a sense of personal inadequacy as well as frustration with the system. Some actually may be inclined to abandon the search altogether at this stage. Exploration is considered the most difficult stage in the ISP when information encountered can increase rather than decrease uncertainty, prompting a dip in confidence.

The fourth stage in the ISP, *formulation*, is the turning point, when feelings of uncertainty diminish and confidence increases. The task is to form a focus from the information encountered. Thoughts involve identifying and selecting ideas in the information from which to form a focused perspective of the topic. A focus in the search process is comparable to a hypothesis in the process of construction. The topic becomes more personalized at this stage if construction is taking place. While a focus may be formed in a sudden moment of insight, it is more likely to emerge gradually as constructs become clearer. During this time, a change in feelings is commonly noted, with indications of increased confidence and a sense of clarity. People often express an awareness of being involved in seeking meaning, such as purposefully engaging in “focusing and narrowing,” in seeking “a thread,” “a story,” “answers to all my questions,” “a central theme,” or “a guiding idea.” The four criteria used to select a topic may be employed again to choose a focus: Task; What am I trying to accomplish? Time; How much time do I have? Interest; What do I find personally interesting? Availability; What information is available to me?

Collection is the fifth stage in the ISP when interaction between the user and the information system functions most effectively and efficiently. At this point, the task is to gather information related to the focused topic. Thoughts are centered on defining, extending, and supporting the focus. Actions involve selecting information relevant to the focused perspective of the topic and making detailed notes on that which pertains specifically to the focus. General information on the topic is no longer relevant after formulation. The person, with a clearer sense of direction, can specify the need for pertinent, focused information to intermediaries and to systems, thereby facilitating a comprehensive search of available resources. Feelings of confidence continue to increase as uncertainty subsides, with interest in the project deepening.

In the sixth stage, *presentation*, feelings of relief are common with a sense of satisfaction if the search has gone well or disappointment if it has not. The task is to complete the search and to prepare to present or otherwise use the findings. Thoughts concentrate on culminating the search with a personalized synthesis of the topic or problem. Actions involve a summary search in which decreasing relevance and increasing redundancy are noted in the information encountered.

ROLE OF AFFECT IN INFORMATION-SEEKING BEHAVIOR

These studies were among the first to investigate the affective aspects or feelings in the process of information seeking along with the cognitive and physical aspects. Prior to the introduction of the ISP, the affective dimension of information seeking had not been fully recognized in library and information services and systems. One of the surprising and important findings in this research was the discovery of a sharp increase in uncertainty and decrease in confidence after a search had been initiated. A person “in the dip” commonly experienced uncertainty, confusion, and anxiety until a focus or a personal perspective had been formed.

The ISP presents information seeking as a process of construction influenced by George Kelly’s personal construct theory.^[2] Information seeking involves construction in which the person actively pursues understanding and seeks meaning from the information encountered over a period of time. The process is commonly experienced as a series of thoughts and feelings that shift from vague and anxious to clear and confident as the search progresses.

Kelly describes the emotional experience of constructing meaning from new information. The information is assimilated in a series of phases, beginning with confusion. Confusion increases as inconsistencies and incompatibilities are confronted between the information and the constructs the person already holds. As confusion mounts, it frequently causes doubt in the ability to assimilate the new information. The disruption caused by the new ideas may become so threatening that the new information is discarded and construction abandoned. At this point, Kelly proposes another alternative to move the process of construction along. The person may form a tentative hypothesis to move toward incorporating the new construct into their existing system of personally held constructs.

The ISP is a process of seeking meaning not just finding and reproducing information. This is a process of construction involving exploration and formulation that rarely proceeds directly from selection to collection. Experience influences the decisions and choices a person makes throughout the process of information seeking.

Studies of the ISP in the workplace reveal that a person’s experience of the stages in the ISP is related to how much the person knows about the problem and the degree of construction that needs to be undertaken during information seeking. In more routine tasks, where the goal is to answer a simple question or to monitor periodic change, people do not usually experience stages in their information seeking. In more complex tasks, where the goal requires considerable construction and learning, people are likely to experience a process as described in the ISP model.^[6]

Focus Formulation as a Pivotal Point in the ISP

The formulation of a focus or personal perspective is a pivotal point in the ISP. Focus formulation calls for reflective thinking about the information encountered in the exploration stage of the ISP that provides a direction for the completion of the search. A focus is a guiding idea to concentrate on to complete the search and accomplish the task.

People often find the period preceding formulation of a focus the most difficult phase in the search process. Exploration is a difficult stage because uncertainty commonly increases, rather than gradually decreasing, during this time. People can experience anxiety and frustration as they encounter information from many different perspectives, much of which may not be compatible with their specific constructs and personal knowledge. The connection between feelings and formulating is evident from the rise in confidence that parallels increased clarity as formulation unfolds. Formulation, the central task in the ISP, is frequently misunderstood when the search process is thought of as merely a process of collection not a construction activity.

Exploration facilitates formulating a focus during the search process. However, people often attempt to move from selection directly to collection without the essential exploration for the formulation that gives direction to the search. Exploring uncovers information for formulating new constructs, whereas collecting gathers information for documenting established constructs. Tolerance for the mounting uncertainty in the exploration stage is important for formulation within the ISP. Using information involves interpreting and creating. No matter the amount or the quality of the information gathered, the problem is not solved or the topic understood until the information has been interpreted. Understanding develops through extending and defining a topic by reflecting on the information encountered to solidify personal understanding.

Acquiring More Information Can Increase Uncertainty

The axiom that information reduces uncertainty is not necessarily the user's experience in information seeking. In some situations, new information actually increases uncertainty. Prior to formulation, users are likely to experience heightened uncertainty in the face of unique, incompatible, inconsistent information that requires construction and interpretation. It seems helpful for users to expect uncertainty to increase during the exploration stage of the ISP rather than thinking that increased uncertainty is a symptom that something has gone wrong. The tolerance of uncertainty is introduced as enabling the early stages of the ISP, when the experience of uncertainty may overwhelm the person and deter progress in the process. Uncertainty from the user's perspective is a natural experience in the search process.

If unexpected, the presence of uncertainty and particularly any increase in uncertainty can heighten anxiety.

Central to the ISP model is the notion that uncertainty, both cognitive and affective, increases and decreases in the process of information seeking. Uncertainty, the predominant experience in the early stages of the search process, had not been sufficiently addressed in library and information services.

PRINCIPLE OF UNCERTAINTY FOR INFORMATION SEEKING

Uncertainty is a cognitive state that commonly causes affective symptoms of anxiety and lack of confidence. Uncertainty and anxiety can be expected in the early stages of the ISP. The affective symptoms of uncertainty, confusion, and frustration are associated with vague, unclear thought about a topic or question. As knowledge states shift to more clearly focused thoughts, a parallel shift occurs in feelings of increased confidence. Uncertainty due to a lack of understanding, a gap in meaning, or a limited construct initiates the process of information seeking.^[8]

The principle is expanded by six corollaries: process corollary, formulation corollary, redundancy corollary, mood corollary, prediction corollary, and interest corollary.

Six Corollaries of the Principle of Uncertainty

1. *Process corollary*: The process of information seeking involves construction in which the person actively pursues understanding and meaning from the information encountered over a period of time. The process is commonly experienced in a series of thoughts and feelings that shift from vague and anxious to clear and confident, as the search progresses.
2. *Formulation corollary*: Formulation is thinking, developing and understanding, and extending and defining a topic from the information encountered in the early stages of a search. The formulation of a focus or a guiding idea is a critical, pivotal point in the ISP when a general topic becomes clearer and a particular perspective is formed as the person moves from uncertainty to understanding.
3. *Redundancy corollary*: The interplay of seeking what is expected or redundant and encountering what is unexpected or unique results in an underlying tension in the ISP. Redundant information fits into what the user already knows and is readily recognized as being relevant or not. Unique information is new and extends knowledge and does not match the person's constructs requiring reconstruction to be recognized as useful. Too much redundant information leads to boredom, whereas too much unique information causes anxiety. The lack of redundancy in the early stages of the ISP may be an

underlying cause of anxiety related to uncertainty. Uncertainty may decrease as redundancy increases.

4. *Mood corollary:* Mood, a stance or attitude that the person assumes, opens or closes the range of possibilities in a search. According to Kelly, an invitational mood leads to expansive, exploratory actions, whereas an indicative mood fosters conclusive actions that lead to closure. The person's mood is likely to shift during the ISP. An invitational mood may be helpful in the early stages and an indicative mood in the later stages. A person in an invitational mood would tend to take more expansive, exploratory actions, while a user in an indicative mood prefers conclusive actions that lead to closure.
5. *Prediction corollary:* The ISP is a series of personal choices based on the person's predictions of what will happen if a particular action is taken. People make predictions derived from constructs built on past experience about what sources, information, and strategies will be relevant and effective. These predictions lead to the choices they make in the stages of the ISP. People develop expectations and make predictions about the sources used or not used, the sequence of source use, and the information selected from the sources as relevant or irrelevant. Relevance is not absolute or constant but varies considerably from person to person.
6. *Interest corollary:* Interest increases as the exploratory inquiry leads to formulation in the ISP. Motivation and intellectual engagement intensify along with construction. Personal interest may be expected to increase as uncertainty decreases. The person's interest and motivation grows as the search progresses. Interest is higher in later stages after the person has formed a focus and has enough understanding of the topic to become intellectually engaged.

IMPLICATION OF ISP FOR INFORMATION SERVICES AND SYSTEMS

Information searching is traditionally portrayed as a systematic, orderly, and rational procedure rather than the uncertain, confusing process that users commonly experience. After the search is completed, the topic understood, and the problem solved, a person may look back and deny the chaos and confusion that was actually experienced in the process. A gap exists between users' expectations in information use and search design.

The ISP considers uncertainty as natural and essential for constructing personal knowledge in the process of information seeking rather than regarding the reduction of uncertainty as the primary objective of information seeking. Uncertainty is a concept that offers insight into the user's quest for meaning within the ISP. If

uncertainty is viewed as a sign of the beginning of learning and creativity, the goal of library and information services shifts from reducing uncertainty to supporting the user's constructive process.

Increased uncertainty in the ISP indicates a need for intervention that enables the person to move on to further construction and understanding. Uncertainty in the ISP indicates a zone of intervention in the ISP for information intermediaries.^[9]

Zone of Intervention for Information Services and Systems

The zone of intervention is a concept modeled on Vygotsky's notion of a zone of proximal development.^[10] Vygotsky, the soviet psychologist whose work has had a profound influence on learning theory, developed the concept of identifying an area or zone in which intervention would be most helpful to a learner. The zone of proximal development is the distance between the actual developmental level as determined by independent problem solving and the level of potential development as determined by problem solving under professional guidance or in collaboration with more capable peers. This concept provides a way of understanding intervention in the constructive process of another person.

The zone of intervention in information seeking may be thought of in a similar way. The zone of intervention is that area in which an information user can do with advice and assistance what the user cannot do alone or can do only with difficulty. Intervention within this zone enables individuals to progress in the accomplishment of their task. Intervention outside this zone is inefficient and unnecessary, experienced by users as intrusive, on the one hand, and overwhelming, on the other.

Taken together, the stages of the ISP, uncertainty principle, and the concept of a zone of intervention propose a conceptual framework for understanding information seeking as a process of construction from the user's perspective. In summary, the ISP model describes the experience and behavior of people involved in extensive research projects. People using libraries and information systems to learn about a particular subject or to investigate a problem or issue often have difficulty in the early stages of information seeking. Even when they begin with great enthusiasm and initial success, many become confused and uncertain as to how to proceed after a short period of time. This is particularly noticeable with students who have been assigned a research paper but is not limited to students. Initial hesitation, confusion, and uncertainty are reported by people in all types of libraries and in the workplace. In fact, we have no way of knowing just how many people give up after initiating a search because they become uncertain and feel incompetent to continue.^[11] It is helpful to understand that a period of cognitive and

affective uncertainty is natural and essential in the early stages of learning from a variety of sources of information.

IMPLICATIONS FOR EDUCATION

The challenge facing educators is to prepare students for learning, living, and thriving in the dynamic, cluttered, and chaotic information environment of today's world. At the core of what it means to be educated today is to know how to learn from a variety of sources of information. The ISP studies found that students need considerable guidance and intervention throughout the research process to enable a depth of learning. Without guidance, students often view research as a simple collecting and presenting assignment that can result in copying and pasting with little real learning. With guidance, students are able to concentrate on constructing new knowledge in the phases of research to gain personal understanding and transferable skills.

Based on the findings of the ISP studies, an approach called Guided Inquiry has been developed with practical strategies and tools that engage and support students in each phase of the research process.^[12] The ISP model has been translated into Guided Inquiry Design, a phased design framework that can be applied by teachers to guide students through the process of learning from multiple sources of information.^[13] The phases of the design framework, *open, immerse, explore, identify, gather, create, share, evaluate*, follow the flow of feelings, thoughts, and actions described in the ISP, as shown in Fig. 2.

Emotions play an important role in learning. Recent brain research confirms that emotions work in

conjunction with thinking in the holistic process of constructing knowledge, as described in the ISP. In Guided Inquiry, a learning team of teachers and librarians concentrate on what students are feeling as well as what they are thinking and doing as they are learning throughout the research process. Students come to realize that feeling uncertain is a normal and necessary part of learning. They acquire strategies to support them during phases of uncertainty and are guided in their efforts to learn in the research process.

CONCLUSION

People engage in an information search experience holistically, with an interplay of feelings, thoughts, and actions. Common patterns of feeling, thinking, and acting are characteristic in each phase. These studies were among the first to investigate the affective aspects or the feelings of a person in the process of information seeking along with the cognitive and physical aspects. Rather than a steady increase in confidence from the beginning of a search to the conclusion, as might be expected, a dip in confidence is commonly experienced once an individual has initiated a search and begins to encounter conflicting and inconsistent information. A person “in the dip” is increasingly uncertain and confused until a focus is formed to provide a path for seeking meaning and criteria for judging relevance. Advances in information technology, which open access to a vast assortment of sources, have not helped the user's dilemma and may have intensified the sense of confusion and uncertainty. Information systems may intensify the problem particularly in the early stages of

Fig. 2 Phases of the design framework.

Source: From Kuhlthau, Maniotes, and Caspari^[12,13]

the ISP by overwhelming the user with “everything” all at once. Increased uncertainty indicates a zone of intervention in the process of information seeking for information intermediaries.

Information Searching and Search Models

Iris Xie

School of Information Studies, University of Wisconsin–Milwaukee, Milwaukee, Wisconsin, U.S.A.

Abstract

It is a critical issue to design information retrieval (IR) systems to effectively support users in their information searching. Users are naturally drawn to systems whose features make their searching easy, intuitive, efficient, and successful. However, there is a gap between user studies and the application of study results to actual system design. This entry serves as a summary of information searching and search models, and calls for the need to incorporate these user studies into system design and testing. Key terms related to information searching and search models are defined. A historic context is provided to illustrate the evolution of the four main digital environments that users interact with in their search process to offer readers background information regarding the transition from manual information systems to computer-based IR systems, as well as the transition from intermediary searching to end user searching. New emerging research areas in information searching are also discussed. Emphasis is placed on the review of different levels of information searching, including search tactics/moves, search strategies, usage patterns, factors affecting searching in relation to tasks, user knowledge structure, IR system design, social-organization context, and search models. Search models are further classified into two types, with one type illustrating information search process and the other type emphasizing the factors that influence the process. In addition, unsolved problems and future research are discussed and suggested.

INTRODUCTION

Since the emergence of the Internet, searching for information has become part of everyday activities for the general public. Successful information searching can only be achieved if information retrieval (IR) systems can effectively support users in their search processes. Users seek out and favor IR systems that make them feel like successful and accomplished searchers in addition to retrieving the information being sought. However, there is a lack of integration between findings of user studies and actual IR system design and evaluation. This entry summarizes information searching and search models, and offers the opportunity for system designers to apply user studies into IR system designs. This entry starts with the definitions of key terminologies in the Introduction, and follows by providing the overview of the historical context portraying the history of the four digital environments. The focus of the entry is on the identification of levels of search strategies ranging from search tactics/moves, types and dimensions of search strategies, and usage patterns to the factors that influence the selection and application of search strategies. More important, this entry presents 11 search models that illustrate the dynamic search process and a variety of variables that define the search process. Finally, future research for information searching and search models is discussed.

Despite their different foci, information searching can also be used as a synonymous term for IR, information

seeking, and information access.^[1] While information seeking refers to purposive behavior involving users' interactions with either manual or computer-based information systems in order to satisfy their information goals, information searching refers to the micro level of purposive behavior when interacting with different types of information systems.^[2] IR is also a broad concept similar to information seeking but is more limited to users' interactions with computer-based information systems. Focusing on intellectual perspectives (information searching, IR, and cross-cutting) and theoretical orientations (information, people, and technology), information searching and IR were systematically compared. Based on the comparison, the authors identified 17 key constructs of information searching and retrieval. While information searching research focuses on users' interacting with specific IR systems, IR research emphasizes information representation, storage, and finding. The two areas gradually converge.^[3] Since research on information seeking and IR has contributed significantly to research on information searching, some of the associated works are also reflected here.

Information searching can be characterized at different levels including tactics/moves, strategies, usage patterns, and models. Tactics or moves are the micro-level behaviors that users exhibit in their search process. Specifically, a tactic is a move that advances the search process. In some studies, a move can be defined narrowly by researchers. For example, a move is termed as any

changes made in formulating a query.^[4] Searching strategies are a combination of tactics or moves. According to Bates,^[5] “A search strategy is a plan for the whole search, while a tactic is a move made to further a search (p. 207).” A search strategy involves multiple dimensions, such as intentions, resources, methods, and so on. Usage patterns identify patterns of query formulation and reformulation based on analysis of transaction logs submitted to electronic IR systems. Search models are illustrations of patterns of information searching and the search process. Some of the models also identify the factors that influence the search process.

Users and online IR systems are partners in the information search process (ISP). Online IR systems can be characterized as IR systems that allow remote access with searches conducted in real time.^[6] Users generally search information from four types of online IR systems: online databases, online public access catalogs (OPACs), Web search engines, and digital libraries. In recent years, users also search information in different types of social media. Information searching can be categorized into intermediary information searching and end user information searching. In intermediary searching, information professionals serve as intermediaries between users and the IR system in the search process, whereas in end user searching, users directly search for information themselves.

HISTORICAL CONTEXT

In order to discuss information searching and search models, we have to first provide a historical context, in particular, the evolution of the four major digital environments that users interact with. The emergence of online databases and OPACs indicates a new era for information searching from manual information systems to computer-based IR systems. The availability of OPACs and CD-ROM databases enabled users to search for information themselves. Later, the Web and the array of information resources to which it provided access made end user searching of IR systems much more widely available. As partners of information searching, the development and evolution of online IR systems to some extent affects how users search for information. That is why it is important to offer a historical context for information searching before presenting a discussion of information searching and search models.

OPACs hold interrelated bibliographic data of collections of a library that can be searched directly by end users. In the 1960s, library automation projects started in university libraries. Computer-based library systems were implemented in large universities by commercial vendors in the 1970s. OPAC systems designed for public access started in the 1980s. Four generations of OPACs have evolved across time, from the first generation of OPACs that followed either online card catalog models emulating the familiar card catalog or Boolean searching models

emulating online databases to the new generation of Web OPACs, which incorporate advanced search features and new designs from other types of IR systems and allow users to search for information resources generated from libraries, publishers, and online vendors.

Online databases consist of full-text documents or citations and abstracts accessible via dial-up or other Internet services. Several dial-up services were offered in the 1960s, and in 1972 commercial online services, such as Dialog and ORBIT, started. Traditionally, online searchers were information professionals who acted as intermediaries between users and online databases. After the creation of the World Wide Web, online vendors began to design Web versions of online services to help end users search for information themselves more easily. Characteristics of the new online database services include easy access, customization, and interactivity.

The emergence of the Web in early 1990 enabled millions of users to search for information without the assistance of intermediaries. Web search engines allow users to mainly search for Web materials. Four types of search engines have been developed to enable users to accomplish different types of tasks:

- Web directories with hierarchically organized indexes facilitate users' browsing for information.
- Search engines with a database of sites assist users' searching for information.
- Meta-search engines permit users to search multiple search engines simultaneously.
- Specialized search engines create a database of sites for specific topic searching.

Many of the Web search engines also offer users the opportunity to search for multimedia information and personalize their search engines. Now, Web search engines also extend their services to full-text books and articles in addition to Web materials. The popularity of Web search engines influences the way that users interact with other types of online IR systems.

Digital libraries collect, organize, store, and disseminate electronic resources in a variety of formats. The availability of online access to digital libraries began in the 1990s. Digital libraries allow users to search and use multimedia documents and can be hosted by a variety of organizations and agencies, either for the general public or for a specific user group. Digital libraries also pose challenges for end users to interact with multimedia information in different interface designs without the same support as of physical libraries.

SEARCH TACTICS AND SEARCH MOVES

Research on information searching has focused on four levels: tactics/moves, strategies, usage patterns, and

models. Tactics are moves that users apply in the search process. Different types of tactics play different roles in assisting users who are searching for information. Based on their functions in the ISP, information tactics can be classified into monitoring tactics, file structure tactics, search formulation tactics, and term tactics. While monitoring tactics and file structure tactics are tactics used to track the search and explore the file structure to find desired information, a source, or a file, search formulation tactics and term tactics are tactics applied to assist in the formulation and reformulation of searches as well as to help select and revise terms in search formulation.^[5] In addition to search tactics, idea tactics assist users in identifying new ideas and resolutions to problems in information searching. While idea generation tactics include think, brainstorm, meditate, etc., pattern-breaking tactics consist of catch, break, breach, and others.^[7] Focusing on topic management, knowledge-based search tactics are another type of tactic that broadens the topic scope, narrows the topic scope, and changes the topic scope.^[8]

Similar to tactics, search moves directly illustrate how users interact with online IR systems. Search moves in general relate to query formulation and reformulations. They can be classified based on whether the meaning of a query has changed. When operational moves that keep the meaning of query components remain unchanged, conceptual moves change the meaning of query components. Conceptual moves are highly associated with search results. The objectives of these moves are to reduce the size of a retrieved set, enlarge the size of a retrieved set, or improve both precision and recall.^[4] Search moves can also be grouped depending on whether the moves are related to conceptual or physical moves. Cognitive moves refer to moves that users conceptually make in order to analyze terms or documents, while physical moves refer to moves that users make in order to use system features.^[9]

TYPES AND DIMENSIONS OF SEARCH STRATEGIES

Search strategies consist of combinations of tactics or moves and can be characterized by types and dimensions. In online databases and OPAC environments, search strategies can be classified by different types: concept-oriented, system-oriented, interactive, active, and reactive strategies. Concept-oriented strategies refer to strategies that manipulate concepts of search topics. The majority of the most-cited search strategies belong to this type. Building block, pearl-growing, successive-fractions, most-specific-facet-first, and lowest-postings-facet-first^[10] represent concept-oriented strategies. Unlike concept-oriented strategies, system-oriented strategies focus on making good use of different system features: the known-item instantiation strategy, the search-option heuristic

strategy, the thesaurus-browsing strategy, and the screen-browsing strategy.^[11]

Search strategies can also be defined by how and to what extent users interact with IR systems and information objects embedded in the systems. Search and browsing are the main strategies users employ when they interact with IR systems. Browsing strategies require more interactions than analytical search strategies.^[12] Active and reactive strategies specify another approach to classifying search strategies. By applying active strategies, users make decisions about how to search for information before the first move, such as author, title, concepts, external support, system features, etc. By applying reactive strategies, users make decisions by following one move after another, such as focus shifts, search term relationships, error recovery, and so on.^[13]

Search strategies in Web search engine environments have their own characteristics. Search strategies that concentrate on query reformulation were generated based on log analysis: specified, generalized, parallel, building-block, dynamic, multitasking, recurrent, and format reformulation.^[14–16] Some of them are similar to search strategies in online database environments, such as specified, generalized, and building-block, but others show unique characteristics of search strategies in the Web search engine environment, such as multitasking, recurrent, dynamic, and others. In Web search engine environments, users sometimes perform different search tasks simultaneously; their searches are more dynamic, and they often apply the same search queries repeatedly. The Web environment also defines the unique design and features of the Web and Web searching. The 10 problem-solving strategies^[17,18] represent search strategies in Web searching: surveying, double-checking, exploring, link-following, back- and forward-going, shortcut-seeking, engine-using, loyal engine-using, engine-seeking, and meta-searching.

In order to further analyze the structure of strategies, researchers have explored dimensions of information-seeking strategies. A multifaceted classification of information-seeking strategies was first developed based on four behavioral dimensions consisting of the goal of the interaction (learn, select), method of interaction (scan, search), mode of retrieval (recognize, specify), and types of resources interacted with (information, meta-information). Each type of information-seeking strategy corresponded to a specific prototype of dialogue structure.^[19,20] The underlying common dimensions of browsing—scanning (looking, identifying, selecting, and examining), resource (meta-information, whole object, and part of object), goal (locate, confirm, evaluate, keep up, learn, curiosity, and entertain), and object (specific item, common items, defined location, general, and none)—were identified to illustrate nine patterns of browsing.^[21] Integrating research and empirical studies in different digital environments, dimensions of information-seeking strategies are

further illustrated by intentions, methods, entities, and attributes of interactions. Twelve types of intentions include identify, learn, explore, create, modify, monitor, organize, access, keep records, evaluate, obtain, and disseminate. Eleven types of methods consist of scan, manipulate, specify, track, select, survey, extract, compare, acquire, consult, and trial-and-error. While entities refer to what users intend to acquire or work on, attributes specify the traits/elements of these entities. Entities contain knowledge, concept/term, format, item/object/site, process/status, location, system, and human. Attributes are associated with entities; for example, specific, common, general, and undefined are attributes of data/information. Different combinations of the four dimensions represent a variety of information-seeking strategies that people engage in within an ISP.^[22]

Researchers further designed prototypes of IR systems consisting of different types of supportive techniques that have been identified, such as database summaries, navigable content tables, results clustering, and fielded query to support multiple types of information-seeking strategies. Moreover, a dialogue structure based on multiple types of information-seeking strategies was implemented into IR system design. The findings show that the supportive techniques and structure provide better support for multiple types of information-seeking strategies.^[23–25]

USAGE PATTERNS

Web searching adds new meaning to research on search strategies, in particular, the analysis of transaction logs. Unlike studies on search strategies, usage patterns identified in Web search engine environments focus on patterns of query formulation and reformulation based on analysis of transaction logs submitted to search engines. Patterns of query formulation and reformulation in Web search environments can be characterized in five ways: 1) short queries, 2) short sessions with minimum reformulations, 3) minimum use of operators and search modifiers, not always used correctly, 4) minimum viewing results, and 5) search topics ranging from entertainment, recreation, and sex to e-commerce.^[26–30] Log analysis is not limited to quantitative analysis; facets of query formulations were identified as well.

Usage patterns in different types of IR environments have also been compared. Both similarities and differences were identified. Short queries, short sessions, minimum view of search results, and similar unique queries were shown in Web search engine, Web page, and digital library environments. Search sessions vary in OPAC environments even though OPAC studies also exhibit short queries. More queries contain Boolean operators in digital library environments than in Web search engine environments.^[31,32] Wolfram and Xie^[33] defined the context of digital libraries as representing a hybrid of both “traditional” IR, using primarily bibliographic resources

provided by database vendors, and “popular” IR, exemplified by public search systems available on the World Wide Web. Usage of online databases in digital libraries reveals that users’ search topics were close to online databases and digital libraries but their search behaviors were more similar to searching Web search engines. In general, users engage in more extensive searching in more traditional IR environments, such as OPAC and online database environments.

Usage patterns in multimedia environments is an emerging area for research. Characteristics of multimedia search can be described as follows: 1) short queries with minimal usage of Boolean operators and advanced features occur frequently. 2) Among all the metadata, media format and copyright information are most searched. User knowledge and media formats affect users’ query formulation and reformulation.^[34–36] Clickthrough data are important indicators of user-system interactions. In particular, they provide implicit relevance feedback by users. Although there is disagreement on the accuracy of clickthrough data, multimedia clickthrough data are much more accurate in general than traditional text search clickthrough data. They have been demonstrated to have the functions of improving searches, suggesting queries, annotating resources, and offering relevance feedback.^[37–39]

More and more people use social media tools in searching and browsing information. In particular, browsing is the dominant user activity across social media. Social browsing is a unique behavior that people employ in using social media tools in which they browse their friend’s updated information, especially images. As a result, browsing friends’ pages increases the interactions among users.^[40–43] However, new users of social media use Facebook as a social searching tool to investigate people they met offline instead of using it as a social browsing tool.^[44] Among all the information in social media, factual, opinion, and recommendation information are the most frequently obtained information.^[45]

FACTORS AFFECTING INFORMATION SEARCHING

Information searching is influenced by different types of factors, in which four main types determine the selection and application of different search strategies: 1) user goal and task, 2) user knowledge structure, 3) design of IR systems, and 4) the social and organizational context.

As to task, complexity of task and stages of task play major roles in influencing search strategies. Task complexity has systematic relationships with the types of information, information channels, and sources needed. As the level of task complexity increases, more information channels and resources are required.^[46,47] Specifically, for a task involving less concepts, either a searching or browsing strategy is applied, although

searching plays a major role, and the interaction process is short; for a task involving more concepts, both browsing and searching strategies are combined, and the interaction process is long.^[48] The task stages, such as initiation, selection, exploration, formulation, collection, and presentation, on the one hand, affect physical actions, cognitive thoughts, and affective feelings and appropriate tasks.^[49] On the other hand, task stages such as prefocus, formulation, and postfocus decide changes in search tactics, term choices, and types of information, as well as relevance criteria.^[50–53] When users move to a more focused stage, they apply more specified search terms, additional operators, and additional tactics. The types of information they search ranging from background information, theories, and models to methods, specific information, and empirical research results. In addition, the familiarity of tasks, timeframe, and types of tasks affect how users plan and apply different types of information-seeking strategies in the IR process.^[54] Research has also demonstrated that different types of search tasks lead to the application of different types of information-seeking strategies.^[55–57]

Three types of knowledge are required for effective information searching: 1) IR knowledge, 2) domain knowledge, and 3) system knowledge. While domain knowledge helps users to develop an in-depth understanding of the search task and what they want, IR knowledge assists users to develop conceptual and procedural strategies.^[58] No doubt, experienced users apply better strategies and perform better than novice users in the ISP.^[59–62] Domain expertise was proved to affect search behaviors and strategies and search performance.^[63–66] Users in different disciplines have their unique characteristics in searching for information. For example, compared with scientists, humanities scholars engage in more searching for individual names, geographical and chronological terms, and unique terms in humanities.^[67] There are also intertwining relationships among different types of knowledge. For example, domain knowledge only influences search tactics of experienced searchers. Simultaneously, domain knowledge of users determines whether their retrieval knowledge has an impact on their search tactics.^[68]

In addition to users' knowledge structure, their cognitive abilities as part of personal information infrastructure, unavoidably, also control their search strategies.^[12] Cognitive styles, learning styles, and searching styles have been demonstrated as the main personal traits that influence search behavior and search performance.^[69–72] Learning styles affect users' selection of search tactics and their interaction strategies with help features of digital libraries.^[73,74] Simultaneously, cognitive styles and users' knowledge structure are interrelated with search performance and search behavior. For example, cognitive styles have more impact on experienced users than on novice users in their interactions with Web search engines.^[75]

The design of IR systems no doubt affects users in their selections of search strategies. Interfaces, computational mechanisms, and information objects are the main

components of IR systems that guide or impede users in their application of different search strategies. As partners of users in the ISP, IR systems—in particular, the design of interfaces—could direct users to more or fewer applications of certain strategies. At the same time, the availability or unavailability of certain features determines whether users could engage in certain strategies. Finally, the information objects that users interact with and the outcomes of interactions might influence their choices of next strategy. Many studies conducted in the Text Retrieval Conferences have compared IR systems with different designs, and the results demonstrate that the design of IR systems makes significant differences in users' application of search strategies and search performances. Researchers have enhanced their IR systems based on the results of the evaluation studies.

The social-organizational context also defines the environment that user-system interactions take place. Mainly, the work environment influences how users determine their search strategies in the search process. Dimensions of a working place, such as the goals and constraints, priorities, general functions, work processes, and physical objects, in particular, priorities, constraints, and business/work cycles, have an impact on users' choices of search strategies.^[54,76] In addition, cultural dimensions shape how users interact with IR systems.^[77]

SEARCH MODELS

Because it is difficult to differentiate search models and retrieval models, in particular interactive IR models as well as some of the information-seeking models that involve search components and process, 11 models in relation to information searching regardless of what terms are used by their original creators are presented here. These search models can be classified mainly into two types. The first type, which mainly illustrates ISPs, includes Ellis' model of information-seeking behaviors, Bates' berry-picking approach, Kuhlthau's model of the ISP, and Workman, Fiszman, Rindflesh, and Nahl's model of serendipitous information search. The second type, which emphasizes the factors that influence the process, consists of Fidel and Soergel's conceptual framework for online bibliographic retrieval, Vakkari's theory of the task-based IR process, Ingwersen and Järvelin's cognitive model, Belkin's episode model of interaction with texts, Saracevic's stratified interaction model, Xie's planned-situational interactive IR model, and Wang, Hawk, and Tenopir's multidimensional model of user-Web interaction. In order to avoid repetition, some of the search models are briefly discussed because they are also presented in other entries.

Ellis' Model of Information-Seeking Behaviors

Ellis^[78,79] developed a behavioral model of the information-seeking behaviors of academic social scientists. This

approach concentrates on the behavior instead of on cognitive activities. The six types of information-seeking characteristics are the key components of the model: 1) starting, 2) chaining, 3) browsing, 4) differencing, 5) monitoring, and 6) extracting. These characteristics cover the overall search process and indicate that users do engage in multiple types of information-seeking strategies. Ellis and Haugan^[80] further modeled the information-seeking patterns of engineers and research scientists in relation to their research activities in different phases and types of projects. Similar behavior patterns were identified from this group of users: surveying, chaining, monitoring, browsing, distinguishing, extracting, filtering, and ending. Ellis' model starts a new behavior approach to identify information-seeking patterns of users and cited widely by researchers who developed other search models.

Bates' Berry-Picking Approach

Continuing her work on search tactics, Bates^[81] illustrated the dynamic search process that searchers went through in the berry-picking approach (Fig. 1). It is one of the most cited approaches that not only identify the limitations of traditional IR models, but also characterize the complexity of the search process. It demonstrates that users engage in multiple information-seeking strategies in their search process. The berry-picking approach can be summarized with four characteristics: 1) searchers' queries evolve; 2) the search process is dynamic as people pick up berries instead of finding one retrieved set; 3) searchers apply multiple search strategies including footnote chasing, citation searching, examining journal runs, area scanning, performing subject and author searches in bibliographies

Fig. 1 Bates' berry-picking approach.
Source: From Bates,^[81] p. 410.

and abstracting and indexing services, and they shift their strategies during the search process; and 4) searchers access resources in different formats and content. The approach also outlines how to implement new search capabilities in the design of online search interfaces. Bates^[82] further developed the cascade model that describes several design layers, which have to be taken into account in the process of system implementation. Design decisions at each layer have a cascading impact on subsequent layers; therefore, the information content, its database structure, and retrievable elements are essential for effective IR. Bates' berry-picking approach sets up the foundation for interactive IR that considers search process as user-system interactions.

Kuhlthau's Model of the ISP

The ISP model was created based on a series of studies of users searching for information in different information-seeking situations.^[49] The ISP model consists of six stages of ISP with affective feelings, cognitive thoughts, and physical actions taken in each stage. The six stages comprise

1. Initiation and recognition of a need to search for information
2. Selection and identification of an appropriate topic or approach
3. Exploration of relevant information on the topic
4. Formulation of a more focused topic
5. Collection of pertinent information
6. Presentation and summarization of search results

Correspondently, affective feelings common to each stage change from uncertainty, optimism, confusion/frustration/doubt, clarity, sense of direction/confidence to satisfaction or disappointment; cognitive thoughts shift from vague to focused with increased interest; and actions range from exploring to documenting in seeking pertinent information. The ISP model has been widely tested and validated in a variety of digital environments.^[50-53,83-85]

Workman, Fuszman, Rindflesh and Nahl's Model of Serendipitous Information Search

Recently, researchers (Workman, Fiszman, Rindflesh and Nahl, 2014)^[86] have investigated serendipitous information seeking and information searching. A model was proposed to illustrate the interaction process occurring in serendipitous information search. It consists of four themes: the iterative process, changes or clarifications of initial information interests, user's prior knowledge, and information organization and presentations. Serendipitous information search is an interactive process including clarifying or changing a current topic, or introducing new topics, etc. The system output needs to be presented in

such a way as to associate users' new knowledge to prior knowledge. Information organization and presentation are the keys to facilitate opportunistic browsing.

Fidel and Soergel's Conceptual Framework for Online Bibliographic Retrieval

Fidel and Soergel^[87] presented a conceptual framework for online bibliographic retrieval. The framework highlights the main factors that affect the search process. Eight elements of the search process and interactions were identified including the setting, the user, the request, the database, the search system, the searcher, the searcher process, and the search outcome. The variables associated with these elements were systematically collected and analyzed: 1) the setting (e.g., organization's orientation, organization affiliations, subject area of the organization, organization mission, etc.); 2) the user (behavior, education, prior experience, attitude, etc.); 3) the request (degree of specificity, degree of difficulty, etc.); 4) the database (coverage, update frequency, thesauri availability, cross-reference listings, cost, etc.); 5) the search system (search aids, search support capabilities, search capabilities, etc.); 6) the searcher (cost consciousness, personality traits, cognitive factors, demographic variables, etc.); 7) the search process (interaction with the user, database selection, query formulation, termination of the search, etc.), and 8) the search outcome (quality of retrieved results, precision, recall, etc.). This framework identifies the main factors affecting online bibliographic retrieval and suggests possible relationships among the variables related to the search process. Although it is created specifically for the online bibliographic retrieval environment, it can also be applied to other digital environments.

Vakkari's Theory of the Task-Based IR Process

Vakkari's theory of the task-based IR process (Fig. 2) considers the ISP as part of the task performance process. This theory is derived from a series of longitudinal studies that investigate students' information-seeking process in their research proposal-writing process for their master's theses.^[50–52,88,89] Based on the results of a series of studies, this model illustrates how the task performance process, in particular stages of ISP, influences the information sought, search tactics applied, terms chosen, operators used, relevance judgments assessed, and documents obtained and used. It further enhances Kuhlthau's model of the ISP in terms of the relationships between stages of task and types of information searched for, changes in search tactics and terms, as well as relevance judgments. This theory systematically presents how tasks have impact on the search process.

Fig. 2 Vakkari's theory of the task-based IR process.

Source: From Vakkari,^[88] p. 58.

Ingwersen and Järvelin's Cognitive Model

Ingwersen and Järvelin^[90] developed a cognitive framework of interactive information-seeking, retrieval, and behavioral processes (IS&R) (Fig. 3) based on Ingwersen's original work^[91,92] on the process of IR interaction. The new research framework places the cognitive actors or teams which bring their organizational, cultural, and social context to the interaction as the major component of the model instead of the searcher as the center of the interaction. The cognitive actors or teams include creators of information objects, indexers, designers of interfaces, designers of retrieval mechanisms, gatekeepers, searchers, and communities representing different groups. While the first four arrows (1–4) present the interaction process, the rest of the four arrows (5–8) reflect the different types of generation and transformation of cognition or cognitive influence. An information seeker's cognitive space, interacting with both social context and IR systems, plays a central role. Interaction and perception are the central processes of the model. "Models" in each of the components reflect the perception of interpretation of their own contexts by any actor or component of the framework in a certain situation. All the participating cognitive structures are interrelated. This is one of the most comprehensive frameworks that reflect the dynamics and complexity of information seeking and the retrieval process as well as associated factors.

Fig. 3 Modified version of Ingwersen and Järvelin's complex cognitive framework of interactive IS&R.

Belkin's Episode Model of Interaction with Texts

Contrary to the traditional view of IR that people can specify their information needs and only engage in one type of information-seeking behavior, Belkin^[93] pointed

out that IR is interaction with texts. He^[94] proposed the episode model interaction with texts (Fig. 4), in which users' interaction with texts is the central process of IR. Belkin and his associates^[19,20] further classified information-seeking strategies into four behavior dimensions

Fig. 4 Belkin's episode model of interaction with texts.

Source: From Belkin,^[93] p. 29.

(the goal of the interaction, method of interaction, mode of retrieval, and type of resource interacted with) and designed a dialog-based IR system that supports different types of information-seeking strategies. In this model, users' goals and tasks are the driving force for IR whereas representation, comparison, navigation, presentation, and visualization are the processes that facilitate users' interaction with texts. This model offers a theoretical framework for understanding how users interact with texts by applying multiple information-seeking strategies, and it further suggests how to design interactive IR systems to support multiple information-seeking strategies.

Saracevic's Stratified Interaction Model

Saracevic^[95,96] proposed and enhanced the stratified interaction model (Fig. 5) in which interaction of the interplay among different levels of users and systems is the central component. While users engage in cognitive, affective, and situational levels of interaction, system involvement includes engineering, processing, and content level. On the cognitive level, the interaction takes place between the cognitive structure of users and texts. On the affective level, users interact with intentions, beliefs, and motivation. On the situation level, users interact with tasks and problems that lead them to look for information. On the engineering level, the process level, and the content level, the hardware, software, and information resources are the foci for analysis, respectively. Users interact with IR systems via interfaces on the surface level by searching, browsing, navigating, organizing, and viewing search results, providing feedback, and other activities. Interactions not only take place at the surface level, but also occur at the deeper levels, which might also lead to changes at the surface level. The complexity and dynamic

interaction process requires changes and adaptations from both the user and system side. The main contribution of the stratified model is its identification of different levels of interactions from both the user and system side and their interplay.

Xie's Planned-Situational Interactive IR Model

Xie^[22] enhanced her previous work^[97,98] on the planned-situational interactive IR model derived from an empirical study. The planned-situational model of interactive IR (Fig. 6) is developed to illustrate how plans and situations codetermine users' applying and shifting different information-seeking strategies in their search process. User goal and task are the driving forces for people to look for information. Four levels of user goals are constructed: 1) long-term goal, 2) leading search goal, 3) current search goal, and 4) interactive intention. Dimensions of the work task (stages, timeframe, and nature) and search task (origination, type, and domain) are identified to characterize tasks. Higher levels of the goal/task impact lower levels of the goal/task. More important, levels of user goal and dimensions of tasks influence how users interact with IR systems. At the same time, information search requires users to apply different types of knowledge and skills into the search process. In addition, the social-organizational context defines the environment in which users interact with IR systems. Users and IR systems are the two partners of information searching. By interacting with the interfaces of IR systems, users interact with the information objects stored in these systems as well as with the computational mechanisms of the software and hardware of the systems.

Information-seeking strategies comprise interactive intentions and retrieval tactics, entities, and associated

Fig. 5 Saracevic's stratified model of IR interaction.

Source: From Xie,^[22] p. 216.

attributes. Planned and situational aspects codetermine the selection and shifts in information-seeking strategies. Three types of situations (routine, problematic, and disruptive) lead to different types of shifts in information-seeking strategies. In a routine situation, the situation can be determined sufficiently with the aid of habitual knowledge. In a problematic situation, after associating the elements of situations with his/her knowledge and plans, further clarification of the open elements of the situation is required. A third type of situation is a “disruptive situation,” in which users do not encounter any problems, but they are distracted during the process of fulfilling their original current search goals/search tasks. The planned-

situational model was tested and validated by empirical studies.^[99–101] This model not only identifies the macro-level components for search and retrieval, but also uncovers shifts in information-seeking strategies and the factors that lead to the selection and shifts in information-seeking strategies at the micro level.

Wang, Hawk, and Tenopir’s Multidimensional Model of User–Web Interaction

Focusing on the Web environment, Wang et al.^[18] proposed a multidimensional model of user–Web interaction (Fig. 7). The model consists of the user, the interface, and

Fig. 7 Modified version of Wang, Hawk, and Tenopir’s multidimensional model of user–Web interaction in IR.

Source: From Wang et al.,^[18] p. 233. Modified by P. Wang, 2008.

the Web space. Among them, the user is the key component. Users are influenced by situation factors, cognitive behavior, affective state, and physical skills. The interface facilitates users' interactions with Web spaces. Access methods, navigation tools, access results/objects, messages/clues, and input/output devices are the elements of the interface. The Web elements contain objects, activated objects, Web spaces, organization schemes, and metadata. This model is further tested and validated by an exploratory study of graduate students' interaction with a university website. They identified approximately ten problem-solving strategies. The findings show that cognitive factors define how users analyze questions, construct search statements, and develop problem-solving strategies; affective factors affect how users adopt and use of strategies; and physical factors determine whether users can engage in efficient interactions. The multidimensional model of user-Web interaction defines how users search for information in the Web environment.

CONCLUSION

Information searching has evolved from searching for information using manual information systems to using electronic IR systems, as well as from intermediary search to end user search. Research has revealed the limitation of traditional IR research: the assumption that information searching is static and people only formulate queries in their search process. Furthermore, research has shown that the ISP is a dynamic one in which people apply multiple types of search strategies. Multimedia search and social media search have their own unique characteristics and challenges. Different levels of information searching, from search tactics/moves to search strategies and usage patterns, have been identified, as well as factors associated with task, user knowledge structure, system design, and the social and organizational context influencing the search process. More importantly, search models have been developed to illustrate either the dynamic search process or major elements that affect the search process. These models also offer suggestions for IR system enhancement and design.

Unsolved problems in research on information searching and search models still exist, however. First, although research on information searching helps reveal the nature of how people interact with different types of IR systems, very few findings of user studies have been applied to the design of IR systems and even less research has been done on testing the new designs. There is a big gap between user-oriented study and system-oriented design. More collaborative work is needed to incorporate and implement the design principles derived from user studies into IR system design and evaluation. Second, a variety of search models have been developed; the problem is that we may not be able to find a

one-size-fits-all model to account for all of the issues in the search process. Further research needs to examine how to integrate different types of search models and identify what is still missing. Third, the newer digital environments call for the need to search for multimedia information and information in different social media. More research is needed to identify search patterns in multimedia and cross-language retrieval. Finally, in order to facilitate users' easy adaptation to different digital environments, future research also needs to compare the similarities and differences of information searching in different digital environments and transform research results into IR system design.

Information Society

Frank Webster

City University, London, U.K.

Abstract

The author problematizes the popular notion of “information society,” and demonstrates that the concept is vague and imprecise, even of dubious value. It may be, therefore, that a good deal of policy today is premised on somewhat shaky foundations. Five different definitions of an information society are presented, each of which presents criteria for identifying the new. These criteria are technological, economic, occupational, spatial, and cultural. The concepts of information and of theoretical knowledge are also addressed within the larger discussion.

INTRODUCTION

It has been commonplace for more than a decade now to say that those of us who inhabit advanced societies such as in North America, Japan, and Western Europe live in an “information society.” The claim that this is so comes routinely from politicians, educationalists, and industrialists, each of whom have concerns about how best to prepare for and compete in this information age. So familiar now is the term information society that it scarcely seems controversial: It is simply part of the accepted vocabulary of opinion leaders who currently comment on the state of the world, a taken-for-granted backcloth to more pressing issues of policy.

For the purposes of this entry, I step back from these more immediate matters deliberately to problematize the notion of the information society. I examine here more precisely than is usual what commentators actually mean when they use the term. As we shall see, when we delve a little, it becomes apparent that the concept is actually vague and imprecise, even of dubious value. Indeed, I shall argue here that the concept information society is inadequate and unhelpful when we try to establish the character of the era in which we live. This suggests, at the least, that a good deal of policy today is premised on somewhat shaky foundations.

We may proceed by distinguishing at least five different definitions of an information society, each of which presents criteria for identifying the new. These criteria are technological, economic, occupational, spatial, and cultural. Let us examine each in turn.

TECHNOLOGICAL

The most common definition of the information society lays emphasis upon spectacular technological innovation. The key idea is that breakthroughs in information

processing, storage, and transmission have led to the application of information technologies (IT) in virtually all corners of society. The major concern here is the astonishing reductions in the costs of computers, their prodigious increases in power, and their consequent application any and everywhere. Because it is now economical and feasible to put computers in typewriters, cars, cookers, watches, factory machines, televisions, kids’ toys... it follows that we are certain to experience social upheaval of such magnitude that we shall enter a new era. Many books, magazine articles, and television presentations have encouraged the development of a distinct genre that offers this viewpoint: the “mighty micro” will usher in an entirely new “silicon civilization.”

Somewhat more sophisticated versions of this technological route to the information society pay attention to the convergence and imbrication of telecommunications and computing (now termed ICT, information and communications technology). In these instances, the argument runs along the following lines: cheap information processing and storage technologies (computers) lead to their being extensively distributed; one of the major areas thus impacted is telecommunications, notably switching centers which, in being computerized, in effect, merge with the general development of computing and impel still more dramatic improvements of information management and distribution. This unification is especially fortuitous because the widespread dissemination of computers means that, for optimum use, they require connection. In short, the computerization of telecommunications means that it is increasingly the case that computer can be linked to computer: hence, the prospect of links between terminals within and between offices, banks, homes, shops, factories, schools, and the globe itself.

This scenario of networked computers is often compared to the provision of electricity: The “information grid” is seen as analogous to the electrical supply. As the electricity grid links every home, office, factory, and shop

to provide energy, so the information grid offers information wherever it is needed. This is, of course, an evolutionary process, but with the spread of an ISDN (integrated services digital network), we have the foundational elements of an “information society.” Once established, these information networks become the highways of the modern age, akin to the roads, railways, and canals of the Industrial Age. As the latter were crucial because they carried back and forth the materials and goods that made the Industrial Revolution, so an ISDN will provide the infrastructure supporting the key ingredient of the Postindustrial Society—information. The rapid growth of the Internet appears to bring about precisely this.

Undoubtedly, what we have here is a technological definition of an information society. Whether it is one that envisages this resulting from the impact of dramatically new technological innovations or as the outcome of a more incremental development of ISDN systems, all perceive technology to be the major distinguishing feature of the new order.

It is very tempting to dismiss technological approaches to the information society out of hand. There has been a surfeit of gee-whiz writing that, awed by the pace and magnitude of technological change, tells us that “the Computer Revolution... will have an overwhelming and comprehensive impact, affecting every human being on earth in every aspect of his or her life.”^[1] The genre of futurism that adopts this tone is characteristically full of “wake up” warnings, shallow analyses of the substantive realm, and the self-assurance that only the author has understood what most others have yet to comprehend. It presents but a poor case for the validity of technological measures.

Nevertheless, it is a recurrent account, one that appears in a seemingly cyclical manner. During the 1980s, amidst interest in the “microelectronics revolution,” this was offered by the likes of James Martin and Christopher Evans, and it gained much media attention. For a while it went out of fashion, only to return with heady talk of an “information superhighway” in the 1990s and in the breathless prose of MIT (Massachusetts Institute of Technology) researcher Nicholas Negroponte.^[2] However, if the likes of Alvin Toffler, Christopher Evans, and James Martin impel one toward rejection of technological criteria, it has to be acknowledged that very many more serious scholars adopt what is at root a similar approach. In Britain, for example, a much respected school of thought has devised a neo-Schumpeterian approach to change. Combining Schumpeter’s argument that major technological innovations bring about “creative destruction” with Kondratieff’s theme of “long waves” of economic development, these researchers contend that IT represents the establishment of a new epoch. This new “techno-economic paradigm”^[3] constitutes the Information Age that is set to mature early in the first century of the millennium.^[4,6]

Elsewhere, Piore and Sabel^[7,8] have suggested that it is the new technologies that provide the foundation for a

radically different way of working—“flexible specialization.” Thanks to communication and computer technologies, and the information edge they give to small firms now able quickly to assess markets and adroitly respond to them, the prospect is for an end to “mass production” and its replacement with customized products made by multiskilled and adaptable craftspeople.

It has to be conceded that, commonsensically, these technological definitions of the information society do seem appropriate. After all, if it is possible to see a “series of inventions”^[9]—steam power, the internal combustion engine, electricity, the flying shuttle, etc.—as key characteristics of the “industrial society,” then why not accept the virtuoso developments in IT as evidence of a new type of society? As John Naisbitt puts it: “Computer technology is to the information age what mechanization was to the industrial revolution.”^[10] And why not?

Technological definitions of the information society must encounter a number of well-founded objections. These include:

1. If technology is the main criterion for defining a society, then why not just call the emerging era a “high-tech society” or an “automated age?” Given the variety of possible ways in which one could describe a society in which IT predominates—Silicon Society? Cybernetic Society? Robotic Age?—why choose to designate it an “information society?” If technology is the key, then it is rather hard to see why it should need the prefix information attached. But then again the “technological society” scarcely evokes the idea of a new, or even significantly different, world that an information society does.
2. When one reads the literature that tells of profound and portentous changes that new technology is bringing about, one cannot but be struck by its palpable presence. Whether it is learning about the impact of the microelectronics revolution in the home, the consequences of robotics for the factory, or the tidal force of a “third wave” of computers, telecommunications and biotechnology that announce “the death knell of industrialism and the rise of a new civilisation,”^[11] there is a self-evident reality about the hereness of the new technologies. Since this is so, and each of us can see it with our own eyes, then it does seem obvious that the technologies are valid as distinguishing features of a new society.

But when one probes further, one cannot but be struck also by the astonishing vagueness of technology in most of these books. Asking for an empirical measure—In this society now, how much IT is there and how far does this take us toward qualifying for information society status? How much IT is required in order to identify an information society?—asking simply for a usable measure, one becomes aware that a good many of those who emphasize technology are

not able to provide us with anything so mundanely real-worldly or testable. It begins to appear, that it is everywhere. . .and nowhere, too.

This problem of measurement, and the associated difficulty of stipulating the point on the technological scale at which a society is judged to have entered an information age, is surely central to any acceptable definition of a distinctively new type of society. It is ignored by popular futurists: The new technologies are announced and it is unproblematically presumed that this announcement in and of itself heralds the information society. This issue is, surprisingly, also bypassed by other scholars who yet assert that IT is the major index of an information society. They are content to describe, in general terms, technological innovations, somehow presuming that this is enough to distinguish the new society.

There are, however, serious scholars who are not content with this and find that the issue of measurement causes considerable obstacles to progress. They encounter two particularly awkward problems. First, how does one measure the rate of technological diffusion, and, second, when does a society cease being “industrial” and enter into the “information” category? These are formidably difficult questions, and ones that should make enthusiasts for the information society scenario hesitate. For instance, in Britain, a decade of social science research by PICT (Programme on Information and Communication Technologies), one charged with mapping and measuring the information society, has not as yet produced any definitive ways of meeting its objectives.^[12,14] Certainly, there have been some advances, with several studies charting the diffusion of some IT into factories and offices.^[15] But how is one to assess this diffusion in more general terms: by expenditure on IT (Yet, given the tumbling prices of the new technologies, how is one to differentiate the economic variable from the more central element of information handling capacity?) or by the amount and range of IT introduced? Ought one to center on IT expenditure or on takeup per head, or is it better to examine this on an institutional basis? How is one to quantify the significance of the expansion of microcomputer applications vis-à-vis mainframe systems? And, if one opts to focus on the uptake of IT, just what is to count as a relevant technology? For instance, should video games come before personal computers, networked systems before robotic applications? Further, while one may be able to imagine a time at which some measures of “informatization” will have been developed that gain widespread assent, one will still be left with the serious query: Where along that graph is the break point that separates the information society from the merely “advanced industrial?”

3. Finally, critics object to those who assert that, in a given era, technologies are first invented and then, subsequently, impact on the society, thereby impelling people to respond by adjusting to the new. Technology in these versions is privileged above all else; hence, it comes to identify an entire social world: the Steam Age, the Age of the Automobile, the Atomic Age.^[16] The central objection here is not that this is unavoidably technologically determinist—in that technology is regarded as the prime social dynamic—and, as such, an oversimplification of processes of change. It most certainly is this, but more important is that it relegates into an entirely separate division social, economic, and political dimensions of technological innovation. These follow from, and are subordinate to, the premier league of technology that appears to be self-perpetuating though it leaves its impress on all aspects of society.

But, it is demonstratively the case that technology is not aloof from the social realm in this way. On the contrary, it is an integral—indeed constitutive—part of the social. For instance, research and development decisions express priorities, and, from these value judgments, particular types of technology are produced (e.g., military projects received substantially more funding than health work for much of the time in the twentieth century West—not surprisingly, a consequence is state-of-the-art weapon systems that dwarf the advances of treatment say of the common cold). Many studies have shown how technologies bear the impress of social values, whether it be in the architectural design of bridges in New York where heights were set that would prevent public transit systems accessing certain areas; the manufacture of cars that testify to the values of private ownership (as opposed to public transport), presumptions about family size (typically two adults, two children), attitudes toward the environment (profligate use of nonrenewable energy alongside pollution), and status symbols (the Porsche, the Mini, the Rover); or the construction of houses that are not just places to live but also expressions of ways of life, prestige and power relations, and preferences for a variety of lifestyles. Again, market power has an obvious influence on what gets manufactured technologically: corporations think of the customers and potential customers prior to production, so it is not surprising that there are limits to what gets made imposed by ability to pay criteria. By the same token, the corporate directors’ dictum, “curb costs, increase productivity, and lose heads,”^[17] has an obvious influence on what the engineers produce, thereby confounding the approach of those who presume that technology is the driving force of change.

There is an extensive literature on this issue that does not need to be labored. All that is required is to state the objection to the hypostatization of technology as applied to the issue of defining the information society. How can it

be acceptable to take what is regarded as an asocial phenomenon (technology) and assert that this then comes to define the social world when it is demonstrable that the dichotomy is implausible because technology is an integral part of the social world?

ECONOMIC

There is an established subdivision of economics that concerns itself with the “economics of information.” From within this, and indeed as a founder of this specialism, the late Fritz Machlup (1902–1983) devoted much of his professional life to the goal of assessing the size and growth of the information industries. Machlup’s pioneering work, *The Production and Distribution of Knowledge in the United States*,^[18] has been seminal in establishing measures of the information society in economic terms. Machlup attempted to trace the information industries in statistical terms. He distinguished 5 broad industry groups (broken down into 50 subbranches), namely:

1. education (e.g., schools, colleges, libraries).
2. media of communication (e.g., radio, television, advertising).
3. information machines (e.g., computer equipment).
4. information services (e.g., law, insurance, medicine).
5. other information activities (e.g., research and development).

Machlup, working with these sort of categories, then attempted to ascribe an economic value to each and to trace its contribution to gross national produce (GNP). If the trend is for these to account for an increased proportion of GNP, then one may claim to chart the emergence through time of an “information economy.” This is just what Machlup proposed in this early study,^[18] which calculated that 29% of the United States’ GNP in 1958 came from the knowledge industries—then a remarkable rate of expansion.

As early as the 1960s, management scholar Peter Drucker was contending that knowledge “has become the foundation of the modern economy” as we have shifted “(f)rom an economy of goods (to) . . . a knowledge economy.”^[19] It is commonplace to argue that we have evolved into a society where the “distinguishing characteristic . . . is that knowledge and organisation are the prime creators of wealth.”^[20]

Probably the best known—and certainly the most cited—study of the emergence of an information economy conceived on these lines comes in a nine-volume report from Marc Porat.^[21,22] In allocating industries to his five categories, Machlup had adopted catholic definitions of “knowledge production,” broadly including those that created new information and those that communicated it. Porat echoed much of Machlup’s approach in his reliance

on government statistical sources to design a computer model of the U.S. economy in the late sixties, but divided the economy between the “primary,” “secondary,” and “noninformation” sectors. This tripartite schema stemmed from his identification of a weakness in Machlup’s approach that failed to account for information activities that were disguised from initial examination; for example, because they are an in-house element of other industries. Porat included in the primary information sector all those industries that make available their information in established markets or elsewhere where an economic value can be readily ascribed (e.g., mass media, education, advertising, computer manufacture). Thus:

The primary information sector includes . . . industries that in some way produce, process, disseminate, or transmit knowledge or messages. The unifying definition is that the goods and services that make up the primary sector must be fundamentally valued for their information producing, processing, or distributing characteristics.^[23]

However, Porat then sought to identify a secondary information sector that would allow him to include in his typology important informational activities such as research and development inside a pharmaceutical company, information produced by government departments for internal consumption, and the library resources of an oil corporation. Thus:

The secondary information sector includes the informational activities of the public bureaucracy and private bureaucracies. The private bureaucracy is that portion of every noninformation form that engages in purely informational activities, such as research and development, planning, control, marketing, and recordkeeping. . . . The public bureaucracy includes all the informational functions of the federal, state, and local governments.^[23]

In this way, Porat is able to distinguish the two information sectors, then to consolidate them, separate out the noninformational elements of the economy, and, by reaggregating national economic statistics, is able to conclude that over 46% of the U.S. GNP is accounted for by the information sector. Ipso facto “The United States is now an information-based economy.” As such, it is an “information society (where) (t)he major arena of economic activity are the information goods and service producers, and the public and private [secondary information sector] bureaucracies.”^[23]

This quantification of the economic significance of information is an impressive achievement. It is not surprising that those convinced of the emergence of an information society’ have routinely turned to Machlup and especially Porat as authoritative demonstrations of a rising curve of information activity, one set to lead the way to a new age.

However, there are difficulties too with the economics of information approach.^[24] One is that, behind the weighty statistical tables that are resonant of objective demonstration, there is a great deal of hidden

interpretation and value judgement as to how to construct categories and what to include and exclude from the information sector.

In this regard, what is particularly striking is that, in spite of their marked differences, both Machlup and Porat create encompassing categories of the information sector that exaggerate its economic worth. There are reasons to question the worth of at least some of these categories. For example, Machlup includes in his “knowledge industries” the “construction of information buildings,” the basis of which presumably is that building for, say a university or a library is distinguishable from construction of warehouses meant to house tea or coffee. But how then is one to allocate the many buildings that, once constructed, change purposes (many university buildings, in the United Kingdom at least, are located in erstwhile domestic houses and stately homes, and one even in a former warehouse)?

Again, Porat is at some pains to identify the “quasi-firm” embedded within a noninformational enterprise. But is it acceptable, from the correct assumption that R&D in a petrochemical company involves informational activity, to separate this from the manufacturing element for statistical purposes? It is surely likely that the activities are blurred, with the R&D section intimately tied to production wings, and any separation for mathematical reasons is unfaithful to its role. More generally, when Porat examines his secondary information sector, he, in fact, splits every industry into the informational and noninformational domains. But such divisions between the thinking and the doing are extraordinarily hard to accept—where does one put operation of computer numerical control systems or the line management functions that are an integral element of production? To be sure, one could say that everything here involves information—and as we shall see, many writers identify the expansion of “managers” and “white collar” work tout court as reason for the coming of an information society—but that is not the point. The objection here is that Porat divides, arbitrarily, within industries, to chart the secondary information sector as opposed to the noninformational realm.

Such objections may not entirely invalidate the findings of Machlup and Porat, and they are not intended to do that, but they are a reminder of the unavoidable intrusion of value judgments in the construction of their statistical tables. As such, they lend support to a healthy skepticism toward ideas of an emergent information economy.

A second difficulty is that the aggregated data inevitably homogenize very disparate economic activities. In the round, it may be possible to say that growth in the economic worth of advertising and television is indicative of an information society, but one is left with an urge to distinguish between informational activities on qualitative grounds. In asking which economically assessed characteristics are more central, are more strategic, to the emergence of an information society, one is requesting scholars to distinguish between, say information stemming from

policy research centers, corporate think tanks, transnational finance houses, manufacturers of 35-mm cameras, software designers, and advertising copywriters.

The enthusiasm of the information economists to put a price tag on everything has the unfortunate consequence of failing to let us know the really valuable dimensions of the information sector. This search to differentiate between quantitative and qualitative indices of an information society is not pursued by Machlup and Porat, though on a commonsensical level, it is obvious that the 4 million daily sales of the *The Sun* cannot be equated with—still less, be regarded as more informational, though doubtless it is of more economic value—the 400,000 or so circulation of *The Financial Times*. It is a distinction to which we shall return, but one that suggests the possibility that we could have a society in which, as measured by GNP, informational activity is of great weight, but that in terms of the springs of economic, social, and political life, is of little consequence. A nation of couch potatoes and Disney-style pleasure seekers consuming images night and day?

Of course, these economists are concerned solely with developing quantitative measurements of the information sector, so the issue of the qualitative worth of information would be of limited relevance to them. However, even on their, own terms, there are problems. One, mentioned earlier, is the question “at which point on the economic graph does one enter an information society?” When 50% of GNP is dedicated to informational activities? This may seem to be a reasonable point, one at which, in straightforward quantitative terms, information begins to predominate. Sadly for information society theorists, however, we are some distance even from that point. Replication studies of Machlup and Porat lead one to qualify any initial sighting of the new age. In a large scale update of Machlup’s study, Rubin and Huber concluded that, in the United States, the contribution of “knowledge industries” to GNP increased from 28.6% to 34.3% between 1958 and 1980, with virtually no change since 1970, this constituting an “extremely modest rate of growth relative to the average rate of growth of other components of total GNP.”^[25] These econometric studies scarcely trumpet the arrival of an information society.

OCCUPATIONAL

A popular measure of the emergence of an information society is the one that focuses on occupational change. Put simply, the contention is that we have achieved an information society when the predominance of occupations is found in information work. That is, the information society has arrived when clerks, teachers, lawyers, and entertainers outnumber coal miners, steelworkers, dockers, and builders. The intellectual groundwork for this conception of the information society was done by Daniel

Bell (1919–) in the 1960s, but it is worth stressing that this definition is presently enjoying much popularity as concern has shifted from a technological measure toward an occupational notion. The emphasis here is on enterprising deal makers, people who “think smart” and quickly in a fast-changing world. Reich^[26,27] has called these “symbolic analysts,” those who do the thinking, planning, innovation, and organization of the “new economy.” They may work in the “creative industries” (media, design, arts), consultancy, or general management, but a popular idea is that such information workers are key to future prosperity. What they have in common is high-level education, and, accordingly, a priority is placed by national governments on the capability of their own education systems to produce such people.^[28]

The occupational definition is frequently combined with an economic measure. Porat, for example, whose work we discussed in the previous section, calculated that by the late 1960s, a little under half the U.S. labor force was to be found in the information sector, a growth of almost 500% during a century in which agricultural employment has plummeted and information occupations have massively expanded. Porat connects the growth in economic significance of information with changing occupational patterns as follows:

In 1967, 25.1% of the U.S. GNP originated with the production, processing, and distribution of information goods and services sold on markets. In addition, the purely informational requirements of planning, coordinating, and managing the rest of the economy generated 21.1% of the GNP. These informational activities engaged more than 46% of the work force, which earned over 53% of all labor income. On the strength of these findings, we call ours an “information economy.”^[23]

On the surface, the changing distribution of jobs seems an appropriate measure. After all, it appears obvious that as work that demands physical strength and manual dexterity, such as hewing coal and farming the land, declines to be replaced by more and more manipulation of figures and text, such as in education and large bureaucracies, then so we are entering a new type of society. Today “(o)nly a shrinking minority of the labour force toils in factories. . . and (t)he labour market is now dominated by information operatives who make their living by virtue of the fact that they possess the information needed to get things done.”^[29]

Most identifiers of an information society draw on occupational changes as indices of the approach of a new age, as many probably as see it in the introduction of new technologies. And, a great number combine the two, regarding new technologies and new informational occupations almost as synonymous. However, it should be noted that the occupational definition is by no means the same as one that identifies an information society by the take-up of new technologies. Many information occupations (e.g., solicitors, teachers) may use little IT,

while many distinctly noninformational jobs have been impacted dramatically by new technologies (e.g., factory operatives, supermarket checkout workers).

The shift in the distribution of occupations is at the heart of the most influential theory of the information society. Here Bell^[30] sees, in the emergence of “white collar society” (and, hence, information work) and in the decline of industrial labor changes as profound as the end of class-based political conflict, more communal consciousness and the development of equality between the sexes.

Robins and I^[31] have criticized Bell’s theorization elsewhere, but here it is appropriate to raise some general objections to occupational measures of the information society. A major problem concerns the methodology for allocating workers to particular categories. The end product—a bald statistical figure giving a precise percentage of “information workers”—hides the complex processes by which researchers construct their categories and allocate people to one or another.

Porat, for instance, develops what has become an influential typology to locate occupations that are primarily engaged in the production, processing, or distribution of information. His is a three-fold scheme that encompasses over 400 occupational types that are reported by the U.S. Census and Bureau of Labor Statistics. He explains it as follows:

The first category includes those workers whose output as primary activity is producing and selling knowledge. Included here are scientists, inventors, teachers, librarians, journalists, and authors. The second major class of workers covers those who gather and disseminate information. These workers move information within firms and within markets; they search, coordinate, plan, and process market information. Included here are managers, secretaries, clerks, lawyers, brokers, and typists. The last class includes workers who operate the information machines and technologies that support the previous two activities. Included here are computer operators, telephone installers, and television repairers.^[23]

Jonscher^[32] simplifies this further still, discerning just two sectors of the economy: the first, an “information sector,” is where people whose prime function is creating, processing, and handling information; the second, a “production sector,” is where workers are found who chiefly create, process, and handle physical goods. These distinctions appear reasonable, precise, and empirically valid, but there are difficulties. Not least is something of which Porat is well aware, namely that “(s)tating precisely who is an information worker and who is not is a risky proposition.”^[23] Indeed, it is, since every occupation involves a significant degree of information processing and cognition. Porat acknowledges this in his attempt to distinguish noninformational from informational labor on the basis of estimating the degree to which each type is involved with information. In other words the categorization is a matter

of judging the extent to which jobs are informational or not. Crude percentages of information workers thus disguise the fact that they are the outcome of the researcher's estimations. As Porat puts it: when "we assert that certain occupations are primarily engaged in the manipulation of symbols. . . It is a distinction of degree, not of kind."^[22]

For example, the railway signalman must have a stock of knowledge about tracks and timetables, about roles and routines; he needs to communicate with other signalmen down the line, with station personnel and engine drivers; he is required to "know the block" of his own and other cabins, must keep a precise and comprehensive ledger of all traffic that moves through his area, and has little need of physical strength to pull levers since the advent of modern equipment. Yet, the railway signalman is, doubtless, a manual worker of the Industrial Age. Conversely, the person who comes to repair the photocopier may know little about products other than the one for which he has been trained; may well have to work in hot, dirty, and uncomfortable circumstances; and may need considerable strength to move heavy machinery and replace damaged parts. Yet, he will undoubtedly be classified as an information worker since his work with new age machinery suits Porat's interpretations.

The point to be made here is simple: We need to be skeptical of conclusive figures that are the outcomes of researchers' perceptions of where occupations are to be most appropriately categorized. As a matter of fact, social scientists know very little about the detail and complexity of people's jobs; there are precious few ethnographies that record the stuff of working lives.^[33] And, researchers trying to label information and noninformation work are just as much in the dark as the rest of their social science colleagues.

One needs also to beware the oversimplifications that can come from allocating a wide variety of jobs to the same pigeonholes. Miles rightly observes that "(t)he categories of work subsumed under the different headings are often extremely heterogeneous."^[34] When one considers, for example, that Porat's first category (information producers) lumps together opticians, library assistants, composers, paperback writers, university professors, and engineers, while his second (information distributors) subsumes journalists on quality newspapers with deliverers on the street, and when the OECD (Organization for Overseas Co-operation and Development) puts together as information producers physicists, commodity brokers, and auctioneers, then one may well have doubts about the value of this composition of occupations as a means of identifying social change. Further, what of the diversity of occupations, each with the same title? Librarian, for example, can encompass someone spending much of the day either issuing books for loan or reshelving returns, as well as someone routinely involved in advising academics on the best sources of information for progressing state-of-the-art research. Again, the title journalist covers a range from hacks specializing in the sex lives of celebrities, cub reporters

describing local weddings, to feature writers whose work can match the best analyses of university professors. Is it really sensible to lump together such diversity?

Finally, an important consequence of this homogenization is a failure to identify the more strategically central information occupations. While the methodology may provide us with a picture of greater amounts of information work taking place, it does not offer any means of differentiating the most important dimensions of information work. The pursuit of a quantitative measure of information work disguises the possibility that the growth of certain types of information occupation may have particular consequences for social life.

I alluded to this distinction when commenting on economic measures of an information society, but it is especially pertinent as regards occupational measures since some commentators seek to characterize an information society in terms of the "primacy of the professions,"^[30] while still others focus on alternative sources of strategically central information occupations. It has to be said that counting the number of information workers in a society tells us nothing about the hierarchies—and associated variations in power and esteem—of these people. For example, it could be argued that the crucial issue has been the growth of computing and telecommunications engineers since these may exercise a decisive influence over the pace of technological innovation. A similar, perhaps even greater, rate of expansion in social workers to handle problems of an aging population, increased family dislocation and juvenile delinquency may have little or nothing to do with an information society, though undoubtedly social workers would be classified with IT engineers as information workers.

Or it may be argued that it is an "inner circle"^[35–37] of corporate leaders, quite different from their predecessors, which is the most decisive index of the information society. These are people who are empowered by communicative skills, analytical abilities, foresight, and capacities to formulate strategic policies, who also enjoy privileged educational backgrounds, connections through shared clubs and boardroom affiliations, plus access to sophisticated information and communications technologies. All of this provides them with extraordinary leverage over social, economic, and political affairs at the national and even the international level. They are information specialists but radically different from the run-of-the-mill information workers with whom crude quantitative methodologists would lump them.

Perhaps we can better understand this need to qualitatively distinguish between groups of information workers by reflecting on a study by social historian Harold Perkin. In *The Rise of Professional Society*, Perkin argues that the history of Britain since 1880 may be written largely as the rise to preeminence of "professionals" who rule by virtue of "human capital created by education and enhanced by... the exclusion of the unqualified." Perkin contends

that certified expertise has been “the organising principle of post-war society,”^[38] the expert displacing once-dominant groups (working class organizations, capitalist entrepreneurs, and the landed aristocracy) and their outdated ideals (of co-operation and solidarity, of property and the market, and of the paternal gentleman) with the professional’s ethos of service, certification, and efficiency. To be sure, professionals within the private sector argue fiercely with those in the public, but Perkin insists that this is an internecine struggle, one within “professional society,” which decisively excludes the nonexpert from serious participation and shares fundamental assumptions (notably the primacy of trained expertise and reward based on merit).

Alvin Gouldner’s discussion of the “new class” provides an interesting complement to Perkin’s. Gouldner identifies a new type of employee that has expanded in the twentieth century, a new class that is “composed of intellectuals and technical intelligentsia,”^[39] who, while in part self-seeking and often subordinate to powerful groups, can also contest the control of established business and party leaders. Despite these potential powers, the new class is itself divided in various ways. A key division is between those who are for the most part technocratic and conformist, and the humanist intellectuals who are critical and emancipatory in orientation. To a large extent, this difference is expressed in the conflicts identified by Perkin between private- and public-sector professionals. For instance, we may find that accountants in the private sector are conservative, while there is a propensity for humanistic intellectuals to be radical.

Our main point here is that both Gouldner and Perkin are identifying particular changes within the realm of information work that have especially important consequences for society as a whole. To Gouldner, the new class can provide us with vocabularies to discuss and debate the direction of social change, while to Perkin, the professionals create new ideals for organizing social affairs.

If one is searching for an index of the information society in these thinkers, one will be directed to the quality of the contribution of certain groups. Whether one agrees or not with either of these interpretations, the challenge to definitions of an information society on the basis of a count of raw numbers of information workers should be clear. To thinkers such as Perkin and Gouldner, the quantitative change is not the main issue. Indeed, as a proportion of the population, the groups they lay emphasis upon, while they have expanded, remain distinct minorities. Tiny in the case of Useem’s “inner circle” and more numerous where the growth of professions is identified but never more than 20% or 25% of the workforce.

SPATIAL
